Examination of the blood disclosed a white-cell count of 13,300, with 83 per cent neutrophils. The urine showed slight trace of albumin, and the sediment contained rare white cells and a few red cells. X-ray examination of the lung fields was negative.

On the following day a large right subpectoral abscess was incised and drained through the axillary route. A large mass of blood clots with some inflammatory tissue and definite pus was found in the space. This was cleaned out and a gauze pack was inserted. A culture of the fluid revealed a hemolytic *Staph aureus*. On the evening of the day of operation the temperature was 99°F and thereafter was normal. The patient was discharged on the 7th postoperative day, having made a good recovery.

The infection in this case, which was due to staphylococcus, was definitely less acute and severe than the streptococcal infections described above. Incision and drainage of the abscess resulted in prompt relief, although the patient could have

been saved a week or more of pain and invalidism by an earlier diagnosis

SUMMARY

A series of 6 cases of acute subpectoral abscess or suppurative lymphadenitis, usually secondary to minor infections in the upper extremity, is reported. This infection is more toxic when due to streptococci than when due to staphylococci or other organisms.

Demonstrable fluctuation is regarded as a late and uncertain manifestation of this syndrome, presumably because the involved lymph nodes may be slow to suppurate and because the abscess when formed is enclosed in a tough fascial envelope deep beneath the pectoral muscles.

Early incision and drainage, which provide the treatment of choice, prevent the extension of the

suppurative process to other regions and bring about rapid subsidence of the infection and almost immediate relief of pain.

Sulfonamide and antibiotic therapy is a valuable adjunct to surgery in this condition, but cannot be relied on to control the infection alone.

ECZEMA VACCINATUM

Report of a Case

A DANIEL RUBENSTEIN, M.D.*

BOSTON

UNTOWARD reactions following vaccination are rare. The clinical entity known as eczema vaccinatum, a type of generalized vaccinia, is one such complication. According to estimates, generalized vaccinia occurs in the ratio of 1 case to 20,000 or 40,000 vaccinations.¹ Because of its rarity, the diagnosis may not be readily apparent. Occasionally, the admission of a patient with unrecognized eczema vaccinatum to the skin ward of a hospital results in an outbreak among those exposed.²

Generalized vaccinia is the term applied to the generalized eruption of typical vaccinal lesions that occur after vaccination. It varies in degree from a mild illness with a few scattered lesions to a severe fatal infection and a clinical course similar to that of smallpox. Eczema vaccinatum occurs for the most part in children with chronic skin disease who have been exposed to cow-pox virus either by vaccination or by contact with a vaccinated person.

It is the purpose of this discussion to present the clinical and laboratory findings in a recent case of eczema vaccinatum. The clinical diagnosis was confirmed by a positive Paul test. Treatment with penicillin, which had been instituted before the illness had been diagnosed, was continued, the purpose being to minimize the possible effects of secondary invaders.

S. H. a 2-year-old boy was admitted to the hospital on May 3, 1946 because of an exacerbation of a cutaneous eruption that had been present for about 6 weeks. The family physician, who was treating the child for eczema of the flexor surface of both elbows and knees, reported that tiny pearl-like lesions had appeared at the periphery of the eczematous areas 4 days before admission. Two days later the lesions had spread over the entire areas previously involved in the eczema. The mother noted flushing of the face and the child appeared quite ill. An older sibling had been vaccinated 13 days before unusual signs and symptoms had been noticed in this patient.

Physical examination revealed a well nourished child who did not appear to be extremely toxic. There was generalized lymphadenopathy. Over the skin of both antecubital and popliteal areas individual lesions had coalesced into a grayish purulent mass (Fig. 1 and 2). At the periphery the pustules were discrete and extended over both arms to the wrists. A few discrete umbilicated pustules were present over the face and lids and in the hair. Physical examination was otherwise negative.

The temperature was 103.4°F, the pulse 110, and the respirations 24.

The red-cell counts on May 4 and 7 were 3,200,000 and 3,540,000 respectively and the hemoglobin determinations on the same days were 10.2 and 12.1 gm. The white counts from May 3 to May 7 varied from 12,500 to 22,400. A smear on May 7 showed 62 per cent neutrophils, 30 per cent lymphocytes, 1 per cent monocytes and 7 per cent eosinophils. A urinalysis on May 4 was negative. A sulfadiazine level of 6.8 mg per 100 cc. was reported on May 7. A culture from a draining lesion revealed a nonhemolytic *Staphylococcus aureus*.

Scraper of the cornea of a rabbit with scrapings of lesions taken on May 6 revealed Giarnieri bodies in epithelial cells scraped from the eye 3 days after inoculation (Fig. 3).

The temperature rose to 105.4°F on the day of admission and fluctuated between 100 and 105°F until May 9. On May 7 several new pustules appeared on the face, legs and

*Instructor in epidemiology, Harvard School of Public Health; district health officer, Massachusetts Department of Public Health.

The Paul test was performed by Dr. Frederic Parker, Jr., pathologist, M. H. Mallory Institute of Pathology, Boston City Hospital.

trunk. On the following day there was a moderate amount of purulent drainage from the lesions in the popliteal and antecubital areas. During that time the patient had become irritable and restless, crying out frequently. As the pustules

has also been noted to Kaposi's varicelliform eruption. Since the first description of this skin disease by Kaposi⁴ there has been a great deal of disagree-

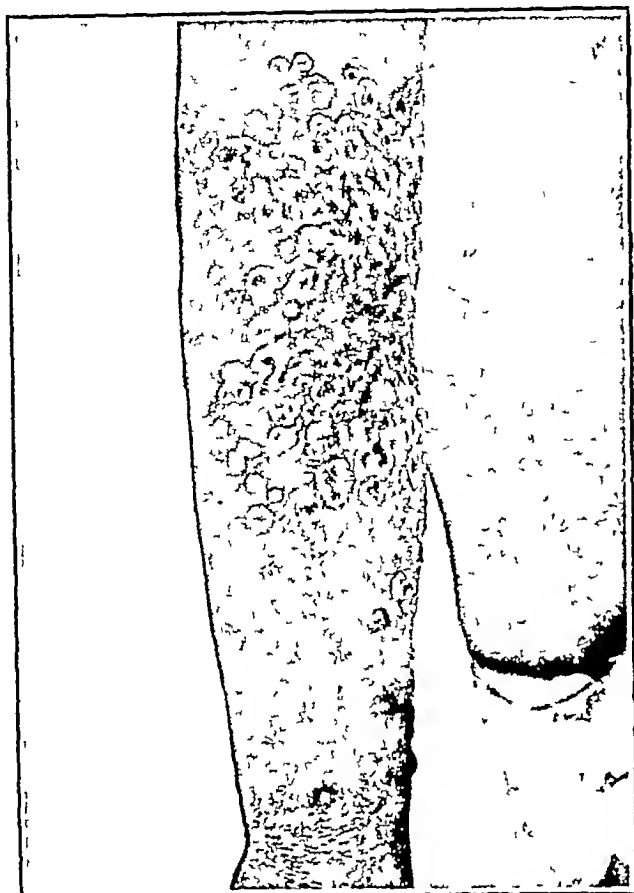

FIGURE 1 *Vaccinal Lesions in the Antecubital Space of the Right Arm*

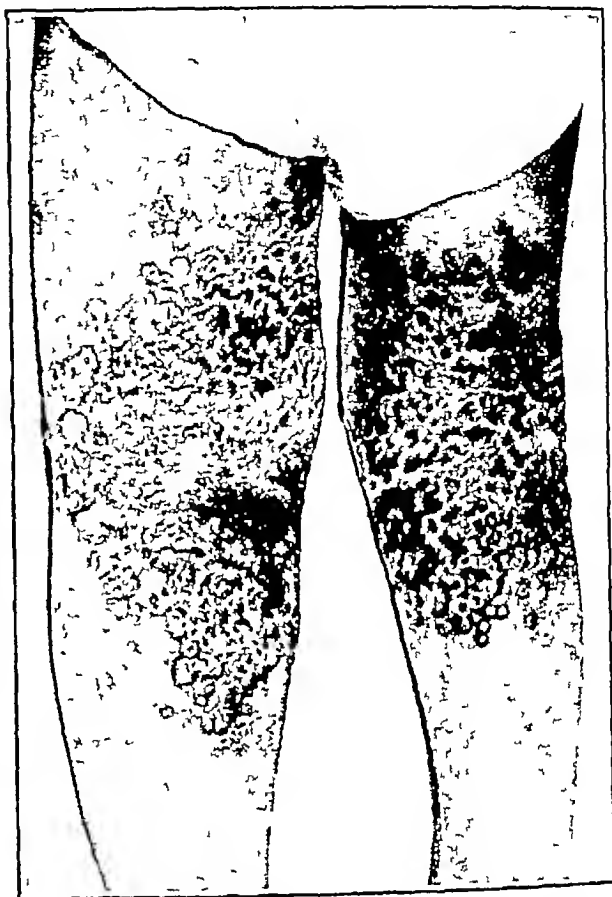

FIGURE 2 *Vaccinal Lesions in the Popliteal Spaces*

dried and scabs formed, the drainage changed from a purulent to a serous exudate and gradually disappeared.

Treatment with penicillin and sulfadiazine was started on admission. Penicillin was administered in a dosage of 10,000 units every 4 hours until May 12, and sulfadiazine in a dosage of 0.5 gm every 4 hours. Chemotherapy was halted on May 7, when a morbilliform eruption appeared on the face and anterior and posterior aspects of the chest. The temperature fell to 98.9°F on May 10 and except for a rise to 102°F on May 12, remained normal thereafter. Recovery was uneventful. No scars were noted at an examination several months later.

Although this patient had not slept in the same bed with the vaccinated child, no attempt at segregation had been made, and there was ample opportunity for direct contact between the children. In addition to direct contact, however, infection of the skin of the eczematous patient by droplet infection must also be borne in mind. In 1929 vaccine virus was demonstrated in the upper respiratory tract four or five days after vaccination.³ Increased susceptibility of patients with skin disease to vaccine virus is well known. In the case reported above the patient himself had not been vaccinated.

Heightened susceptibility of eczematous children

ment concerning its causation and relation to eczema vaccinatum. When there has been no

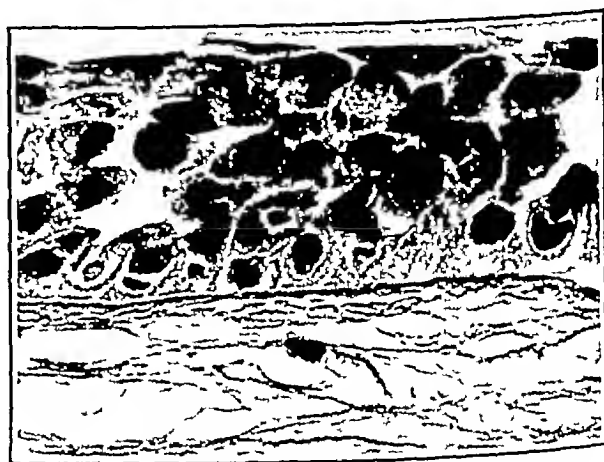

FIGURE 3 *Photomicrograph Showing Guarnieri Bodies in the Epithelial Cells of the Rabbit's Cornea*

history of vaccination or of contact with a recently vaccinated person, the diagnosis of Kaposi's vari-

celliform eruption is usually made. The isolation of herpes virus from patients ill with the latter infection⁷⁻⁹ has differentiated it from eczema vaccinatum, which is of course due to the vaccine virus.

Outbreaks of both eczema vaccinatum and Kaposi's varicelliform eruption have occurred on skin wards following the admission of patients suffering from this infection. Danziger² reported such an outbreak on the open ward of an infants' hospital in which 5 out of 6 children with skin disorders contracted vaccinia after the introduction of a patient with generalized vaccinia. McLachlan and Gillespie⁸ described an outbreak of Kaposi's varicelliform eruption in which 16 cases occurred in a dermatologic ward under similar circumstances.

Chemotherapy has been employed in the treatment of both infections for its possible effect on secondary invaders. For the same reason penicillin was used in the treatment of the patient described above.

A case fatality rate of 33 per cent has been reported for eczema vaccinatum.⁶ Although the clinical course is mild in some cases, patients whose illness is complicated by secondary pneumonia or severe skin infection may be quite ill. It is possible that penicillin has considerable influence in reducing the high case fatality rates associated with eczema vaccinatum.

One or two simple precautions concerning vaccinations must be re-emphasized. Vaccination should be deferred on patients with skin disorders until

recovery has occurred. Vaccinated persons should not be allowed to be exposed to patients suffering from skin infections. If these simple rules are observed the exceedingly low incidence of generalized vaccinia will be reduced to an even greater extent.

SUMMARY

A case of eczema vaccinatum is presented in which the infection occurred as a result of contact with a vaccinated sibling. The clinical diagnosis was confirmed by a positive Paul test.

Precautionary measures, such as deferring vaccination of patients with skin disorders and preventing exposure of such patients to vaccinated persons, will reduce to an even greater extent the present low incidence of generalized vaccinia.

SUBPHRENIC ABSCESS FOLLOWING PRIMARY CLOSURE FOR PILONIDAL SINUS*

Report of a Case

ELLIOTT S. HURWITT, M.D.*

NEW YORK CITY

THE problem of the proper management of pilonidal sinus has occupied a position of increasing importance in the medical literature in the past six years. In the medical care of an active military force of several million generally healthy men and women, pilonidal cyst and sinus have been among the most frequent surgical causes of disability. It is the purpose of this communication to indicate some of the hazards attendant on the primary closure of pilonidal wounds.

Before the war the surgical procedure in widest usage was radical excision, a granulating wound being left to heal by secondary intention. Primary closure of a pilonidal wound had been advocated by some but in general had been given up because of a disturbing number of recurrences (or so-called "persistences") and an occasional severe infection in the sutured wound. Contributing to these complications were the tendency to limit the extent of the excision to preserve tissue for the closure, technical difficulties in obliterating the dead space, the location of the operative field in a region prone to perspire freely and in proximity to the rectum and anus, and perhaps a failure adequately to evaluate the extent of inflammatory changes present at the time of operation.

With the advent of chemotherapy—first, the sulfonamides, followed by penicillin and more recently by streptomycin—there occurred renewed interest in attempts at primary suture of the pilonidal wound. This approach received a tremendous impetus during the war years, when it was considered important to eliminate the loss of time necessary for the healing of a granulating wound. The objective of returning a man to active duty as soon as possible led to a policy of primary closure in a large proportion of cases in almost every service hospital. The ready availability of the chemotherapeutic agents for the control of infection lent courage to these efforts.

That no single method of primary suture has been pre-eminently successful is evidenced by the great number and variety of procedures devised to meet the problem. One of the most promising techniques for obliterating the dead space is that of utilizing gluteal muscle—fascial flaps, as described by Pope¹ and further reported by Holman.² The latter advocates avoiding skin-penetrating sutures and completes the closure with a subcuticular

stitch of wire or dermol. The use of silk is recommended by Dunphy and Matson.³ Cotton has been employed by Ziegler et al.⁴ and Larkin⁵ finds stainless steel the material of choice. All these authors stress the value of meticulous operative technique and care in the postoperative management in lowering the recurrence rate, whether primary closure has been performed or the wound permitted to heal by granulation. There is general agreement that only about 60 per cent of cases are suitable for primary closure and that the recurrence rate with primary closure is slightly higher than that with the more tedious granulating process. Burns,⁶ in a study of civilian cases, reports some success with various methods of closure but finds that the most generally effective results have been obtained by permitting the wounds to granulate. It is difficult to evaluate the end results among service personnel because of the limitations imposed by military conditions on an adequate follow-up study.

The emphasis on primary closure and the protection afforded by chemotherapy have tended to minimize the potential risk entailed in this procedure. The following case, in which a fatal result from overwhelming infection was averted by a narrow margin, is an example in point. The multiple operations were performed by various members of the surgical service of a large naval hospital.

W. R., a 17-year-old seaman, entered the hospital on March 5, 1945, because of a small draining sinus in the intergluteal cleft, with a narrow surrounding area of induration. Under treatment with Sitz baths the inflammatory reaction subsided rapidly, and drainage from the sinus ceased. Ten days after admission, under procaine spinal anesthesia, the cyst was excised en bloc, together with an ellipse of overlying skin. The cyst extended to the lower end of the coccyx and penetrated the coccygeal bone for a short distance. The fascia was closed with interrupted sutures of chromic catgut. Skin closure was performed with figure-of-8 sutures of No. 32 steel wire, and the wound was not drained.

Two days after operation the temperature rose to 102°F, associated with wound pain and tenderness. The sutures were removed, and the infected wound was packed widely open. During the next 4 days discharge from the wound became profuse and foul-smelling, the temperature rose to 104°F, associated with a pain in the right posterior portion of the chest. On the 5th postoperative day there was marked peripheral collapse and delirium, the pulse was 138, the respirations 55, and the blood pressure 80/60. The chest pain continued, but there was no cough or expectoration, and there were no abnormal physical signs referable to the thorax. The abdomen was rigid, and there was no pain, tenderness or vomiting, flatus and loose stools were passed. There was no pain or tenderness of the extremities. The white-cell count was 13,800, with 71 per cent neutrophils and 12 per cent band forms, the hemoglobin was 13.5 gm. A roentgenogram of the chest showed clouding of the right lower-lung field.

*Adjunct surgeon for pediatric surgery, Mt. Sinai Hospital, lieutenant (MC), U.S.N.R.

The patient ran a septic course with swinging temperatures to 106°F and marked rapid deterioration in his general condition. At no time were shaking chills noted and blood cultures were consistently negative for both aerobic and anaerobic organisms. Intensive supportive therapy included maintenance of fluid and electrolyte balance by means of parenteral fluids containing glucose salt, vitamins calcium, plasma and Amlgen, fourteen transfusions of whole blood and oxygen. Chemotherapy consisted of 20,000 units of penicillin every 2 hours intramuscularly supplemented by 40,000 units of penicillin and 6 gm of sodium sulfadiazine by the intravenous route daily. The total amount of penicillin given was 8,100,000 units and that of sulfadiazine 120 gm.

It was the clinical impression that a retroperitoneal cellulitis accounted for the extreme toxicity and abdominal rigidity. An indurated area in the right infrascapular region was incised on April 5, and necrotic foul-smelling tissue was encountered. On April 28 there was a sudden profuse drainage of foul-smelling greenish yellow pus from this wound. Roentgenograms showed pooling of lipiodol in the right subphrenic space. Fluoroscopy demonstrated that the right leaf of the diaphragm was elevated and fixed. A diffuse haze occupied the right lower-lung field.

The diagnosis of a large right subphrenic abscess was then established. Expectoration of foul-smelling material similar to that on the dressings indicated a bronchopleural fistula. On May 2 an incision was made in the right mid-axillary line over the ninth interspace. The pleura was pushed aside, the fibers of the diaphragm were separated with a clamp and a large quantity of foul-smelling yellow grey pus was evacuated. This was positive on culture for *Escherichia coli*, *Streptococcus faecalis* and *Staphylococcus aureus*. Copious amounts of pus drained from this site for 2 weeks, and the temperature elevations fell to between 102° and 103°F. The expectoration of purulent material promptly ceased and did not recur. On July 27 a thoracotomy and rib resection were performed, a chronic empyema sinus being unroofed. After this procedure the patient became afebrile, and there was rapid and steady improvement. By November 15 all the wounds had healed and the weight had risen to 158 pounds from a low of 104 pounds. The pilonidal wound had been completely epithelialized within 3 months of the original operation. The patient was discharged from the hospital 1 year after an operation generally classified in the "minor" category. A follow up letter 10 months later disclosed that he was experiencing no restriction of his activities there had been no recurrence of the pilonidal cyst.

It is apparent that any operative procedure that possibly entails the sequelae experienced in the case presented above is not to be considered lightly. It may be contended that this case was not suitable for primary closure, yet the inflammation present on admission was only moderate in degree and subsided rapidly before the operation was undertaken. The objections that chemotherapy should have been instituted before operation and that larger doses should subsequently have been exhibited may be valid. The combination of *Esch. coli*, *Str. faecalis* and *Staph. aureus*, however, is one

against which it would be difficult to issue a guarantee of protection with the means currently available. Contamination of the wound presumably occurred as the result of injury to the rectum, either during the process of mobilization of the cyst or in the placing of the deeper sutures. Such an accident may easily pass unnoticed.

Sweeping conclusions regarding the merit of a surgical procedure would certainly be hazardous on the basis of a single accident such as this. Careful selection of cases, meticulous operative technique and the judicious exhibition of chemotherapeutic agents may all contribute to the elimination of a large part of the risk incurred when primary closure of a pilonidal wound has been performed. It is suggested, however, that packing the wound widely open and permitting healing by granulation be considered the method of choice in the hands of the inexperienced operator or when there is any evidence of recent inflammation in the local lesion.

SUMMARY

A case of pilonidal sinus treated by excision and primary closure is presented.

The postoperative course was characterized by a fulminating retroperitoneal cellulitis, right subphrenic abscess, bronchopleural fistula and empyema. Although recovery was ultimately effected, a fatal issue was narrowly averted.

It is suggested that the primary closure of pilonidal wounds be reserved for cases conforming to limited criteria. In the hands of the less experienced surgeon, or in the presence of recent inflammation, the procedure of total excision, packing the wound widely open and permitting healing by granulation may be indicated.

MEDICAL PROGRESS

CHEMICAL FACTORS IN ASTHMA (Concluded)*

JOHN G. WISWELL, M.D.,† AND FRANCIS M. RACKEMANN, M.D.‡

BOSTON

BLOOD SUGAR

Numerous investigators have thought that there might be a disturbance in the metabolism of sugar in patients suffering from asthma and allergic conditions. In 1924 Ramirez, St. George and Moses⁴³ examined the levels of the blood sugar in 40 patients, 28 of whom had asthma and hay fever. Determinations were made before and after treatment, but they revealed no uniform differences in the levels of the blood sugar at these two periods.

In 1929 Malone⁴⁴ found the average fasting level of blood sugar to be 75.4 mg per 100 cc in 15 patients with allergic asthma associated with food sensitivity. In 1933 Black⁴⁵ reported an average fasting blood sugar level of 78.9 mg per 100 cc in 100 patients who had a definite history of allergy, and he concluded that more than half the patients with hay fever and asthma have fasting blood sugar values below the normal range and that the sugar tolerance is definitely elevated.

In 1936 MacQuiddy, McIntyre and Koser⁴⁶ published their findings of fasting blood sugar levels and tolerance curves on 20 patients with asthma and hay fever and 21 normal subjects used as controls. They found no significant difference between the two groups. In 1937 Wagner and Rackemann⁴⁷ studied the blood sugar in 24 patients with asthma and hay fever, using both venous and capillary bloods. In all cases the fasting blood sugar and the glucose-tolerance curves were essentially normal.

In 1939 Waldbott, Ascher and Rosenzweig⁴⁸ attempted to make a more crucial study. They selected a group of 14 patients sensitive to pollen who were given a slight overdose of pollen extract. During the mild general reaction that supervened, the blood sugar was determined at intervals of fifteen minutes. The values showed an immediate transient rise followed by a prolonged fall to an average level of 63 mg per 100 cc, which took over two hours to return to the basic level. When the same procedure was carried out on 24 patients who did not develop any reaction to the pollen dose, the blood sugar remained steady. Also, in 22 nonallergic persons who were given pollen injections corresponding to the amounts received by the allergic group, the blood sugar did not change.

In 1939 Joseph⁴⁹ had a different concept. He treated 104 patients, of whom 96 had asthma and

34 had arthritis or arthrosis, with eight to twelve daily injections of 8 units of insulin, and he claimed that the patients improved.

In 1941 Abrahamson⁵⁰ suggested a reciprocal relation between asthma and diabetes. Asthma patients were made worse by sodium chloride, and diabetic patients better, the former were prone to hypothyroidism, and were relieved if they developed hyperthyroidism, the reverse being true for the latter. The two diseases, although frequently occurring among members of the same family, were mutually exclusive and were rarely observed in the same person at the same time. Asthma attacks occurred with a tendency to hypoglycemia, and drugs relieving asthma raised the level of blood sugar. The author assumed that bronchial asthma was associated with hyperinsulinism, as the glucose-tolerance curves of 12 patients with asthma corresponded to those found in cases of hyperinsulinism. The patients improved on high-fat, low-carbohydrate diet, and this fact was supposed to justify the claim that hyperinsulinism was one of the conditions necessary for the appearance of asthmatic attacks. It was a logical explanation for the frequency of nocturnal asthma attacks when the blood sugar level was low, and it explained the failure of glucose to effect a lasting remission. Vollmer,⁵¹ on the other hand, in 1935 had treated 7 children with severe asthma with a course of fifteen to twenty-five injections of insulin, the doses being regulated for each child so that the symptoms of shock were not too severe. Most children were at least temporarily benefited—especially those treated at home with no change in environment. This improvement was attributed to the secondary endogenous production of adrenaline, which improved the asthmatic symptoms. Others have also claimed improvement of asthma by the use of insulin shock therapy.

The evidence cited so far does not show that a low blood sugar level is a cause of the asthma attack. The figures of Malone⁴⁴ and Black⁴⁵ do not fall below 70 mg per 100 cc, which is generally accepted as the point below which a state of hypoglycemia exists. Falling blood sugar values in allergic shock could also occur in almost any type of shock. How low is the blood sugar level at the onset of a nocturnal attack of asthma? Patients with asthma who miss a meal during the day probably have a fall in blood sugar but do not necessarily suffer an acute attack of asthma.

*From the Allergy Clinic, Massachusetts General Hospital.

†Research fellow in medicine, Massachusetts General Hospital.

‡Physician and chief, Allergy Clinic, Massachusetts General Hospital, lecturer in medicine, Harvard Medical School.

lthough blood sugar levels in patients have not been reported at the time when a severe attack occurs, these persons are often unable to eat, and consequently the blood sugar must fall, this, however, is a result rather than a cause of the asthma. Again, why should injections of insulin or insulin-shock therapy improve asthma when the effect is a hypoglycemia? There is no proof that such improvement does take place, Joseph's⁴¹ patients probably gained in health because of a better appetite. No regular schedule of injections of insulin was maintained, levels of the blood sugar were not followed regularly, no glucose tolerance tests were done, and some patients had other forms of treatment as well. Thus, the answer to the causes of asthma is not likely to be concerned directly with the blood sugar level.

CHOLESTEROL AND FAT METABOLISM

Cholesterol is an essential constituent of all cells and fluids of the body. It is concerned with the metabolism of fat, and a disturbance in the metabolism of fat has been considered a factor in the cause of eczema. In 1933 Hansen⁴² studied the blood content of cholesterol and fatty acids in 5 normal infants and in 6 infants with eczema. The levels of cholesterol and total fatty acids in the blood serum were slightly less in the cases of eczema than in the control infants, although still within the normal range. The average iodine number of the serum fatty acids in the eczema group was 84, and in the control group 111, indicating that the serum fatty acids were less unsaturated in infantile eczema than in the control infants. The author assumed that unsaturated fatty acids played a role in the etiology of infantile eczema. In 1936 Bullen and Bloor⁴³ determined the total fatty acids, the cholesterol fatty acids and the iodine number — by the same method that Hansen⁴² had used — on 14 patients with hay fever or asthma who also had had eczema in infancy and on 12 nonsensitive subjects in the same age group. The averages of the results were nearly identical in the two groups. There was no definite difference in the degree of unsaturation of the plasma fatty acids. Thus, the feeding of unsaturated fats appears to be of no therapeutic value in asthma and hay fever. Bloor, Blake and Bullen⁴⁴ then did further work on the fractions of the total fatty acid, neutral fat, phospholipids and cholesterol esters in 14 patients with asthma, 11 with hay fever, 1 with contact dermatitis and 1 with chronic urticaria, as well as in 5 normal persons. No definite differences were found in the nature of the fatty acids in the three classes of sensitive patients and in the nonsensitive subjects. On the other hand, marked differences were observed in the degree of unsaturation in the three groups of compounds. In the cholesterol esters the fatty acids were much more unsaturated than in the phospholipids or in

the neutral fat, and in the phospholipids the fatty acids were somewhat more unsaturated than in the neutral fat. Cholesterol appears to have a special function in the metabolism of the unsaturated fatty acids, but what this is and what it has to do with allergy the authors do not state.

In 1937 Bruger and his collaborators⁴⁵ determined the levels of cholesterol in the bloods of 49 patients with hay fever and 50 patients with asthma under treatment. They found that there was a tendency for the total blood cholesterol to be slightly elevated above the average normal in patients with treated hay fever and slightly below normal in those with treated asthma. In both groups the percentage of free cholesterol in total cholesterol was definitely elevated above the average normal. In 1938 Chobot and Dundy⁴⁶ measured the levels of cholesterol in the blood of 35 allergic and 25 nonallergic children and observed that 12 allergic children had values above 200 mg per 100 cc. Since a high blood cholesterol may suggest hypothyroidism, they tried therapy with desiccated thyroid in these children but produced no benefit.

Since the metabolism of cholesterol is so little understood, it would be difficult to say on the evidence at present available that cholesterol is concerned with allergy. The idea that the fat metabolism is concerned with the fundamental nature of allergic sensitivity is an attractive thought, but it cannot be supported as yet. A paper by Burr has suggested that the feeding of linseed oil, which contains predominately unsaturated fatty acids, to infants with atopic eczema is beneficial. This treatment has been given to only a few patients so far, but in most of these the eczema has been improved, and the method deserves further study. One notes that except for Hansen's report, the work on fats in allergy has been done on patients with asthma and hay fever rather than on patients with eczema.

THE VITAMINS

Vitamin C

Another attractive theory about the causes of allergy has been that vitamins play a part — either a deficiency in feeding or a faulty absorption and utilization. Ascorbic acid is a reducing agent and is believed to function as a respiratory catalyst in oxidation phenomena in the cells of the body tissues. In 1936 Solomon⁴⁷ claimed that vitamin C administered prior to sensitization with horse serum protected guinea pigs against anaphylactic shock. In contrast, however, Dragstedt, Eyer and Ramirez⁴⁸ failed to show that vitamin C protected dogs against peptone shock or against anaphylactic shock after sensitization with horse serum. In a series of experiments with guinea pigs Van Niekerk⁴⁹ concluded that a deficiency of vitamin C had no influence on the development of anaphylactic sensitization to horse serum. Preliminary

treatment with vitamin C did not protect the animals against shock, nor did the addition of vitamin C to the horse serum hamper the shock action. In a different experiment Cohen⁶⁰ reported that vitamin C deficiency induced by feeding 25 guinea pigs only 20 to 64 per cent of the daily requirement did not prevent the development of anaphylaxis.

Beginning about 1938, ascorbic acid was used rather widely in the treatment of patients with allergic symptoms. Hunt⁶¹ treated 25 patients with asthma with 100 mg of ascorbic acid daily for several weeks, those with acute symptoms were given 500 mg parenterally. In no case was any improvement noted in the amount of wheezing, in the incidence of attacks or in the general condition. In 1941 Goldsmith, Ogaard and Gowe⁶² found the fasting blood level of ascorbic acid in 29 patients with bronchial asthma to be 0.410 ± 0.051 mg per 100 cc, a subnormal level being found in 19 cases, the level in a control group was 0.602 ± 0.049 mg per 100 cc. During a period of several months on a standardized regimen 6 of 7 patients with bronchial asthma were unable to maintain a blood ascorbic acid level of 1.0 mg per 100 cc or more, whereas members of a control group maintained such a level in most cases. These findings were interpreted as indicating that there is an increased requirement for vitamin C in patients with asthma.

In 1942 Holmes and Alexander⁶³ found the urinary output of vitamin C in 25 patients with hay fever (10 mg per 100 cc) to be below the amount excreted by average healthy persons (30 to 50 mg per 100 cc). This indicated a low level of vitamin C in the body, which was probably due to inactivation or destruction of the vitamin. On treatment with 100 to 500 mg of vitamin C daily 88 per cent of the patients reported a gain in health. Pollen counts continued to be high during the period of study. Hebal⁶⁴ treated 9 proved cases of hay fever with 500 mg of vitamin C daily and noted no beneficial effects. He did no determinations of the vitamin C levels in blood serum and urine, and the patients had no other form of treatment at the time the study was done. Friedlaender and Feinberg⁶⁵ treated 43 patients with hay fever with 500 mg of vitamin C daily and observed no beneficial results. Blood levels of vitamin C were determined on patients with and without vitamin C therapy, and were found to be within the normal range. Large doses of vitamin C produced the usual saturation blood levels of 1 mg per 100 cc. Ruskin,⁶⁶ in 1945, reported 27 cases of hay fever and asthma treated in 1944 with 250 to 750 mg of vitamin C daily by mouth. Of these, 20 (74 per cent) were improved, although the pollen count was higher in 1944 than in 1943. Nine of 11 patients receiving desensitization also reported that their symptoms were milder while they were taking the vitamin C. The author concluded that vitamin C was valuable in allergy — even superior to desensitization — and that allergic

disturbances were related to nutritional deficiencies primarily that of ascorbic acid.

Niacin is believed to be a component of coenzyme that act in glycolysis and cellular respiration also acts as a vasodilator and increases circulation of the blood. In 1941 Maisel and Somkin⁶⁷ treated 21 patients having severe asthmatic paroxysms with 0.1 gm of niacin intravenously and produced relief of symptoms in 16 patients. Of 9 chronic asthmatic patients who received 0.2-gm doses of niacin orally, 5 were benefited. The authors do not know the exact mechanism of action of niacin in these cases, but they had no reason to believe that a vitamin deficiency existed. In 1941 Melton⁶⁸ gave 50 or 100 mg of niacin intravenously to 19 patients during acute paroxysms, with definite improvement in 16 cases. The drug was also given orally in doses of 50 to 100 mg two or three times daily to 30 patients who had frequent paroxysms. Frequency and severity of attacks were reduced in 16 cases. Flushing and other symptoms produced by niacin appeared in some cases. The authors thought that the action of the drug in dilating blood vessels was accompanied by a similar action on bronchioles.

In general, then, one must observe that patients with asthma are often undernourished and require an increased amount of vitamins for recovery of general health. In addition, it must not be forgotten that in other conditions in which metabolism is increased, such as prolonged exercise, infection and chronic debilitating diseases, more vitamins are required by the body. Many nonallergic persons with low levels of vitamins in the body experience a gain in health on treatment with doses of these vitamins. Ruskin⁶⁶ did not make a control series of cases treated by desensitization alone; he did not discuss the general health of patients, their dietary habits or changes in weight. His proof that vitamin C therapy in these patients was the dominant factor in the improvement therefore not conclusive. The action of niacin on asthma does not seem to be on a basis of vitamin deficiency, but is possibly due to its vasodilator effect. Deficiencies of vitamin C or niacin, are probably not contributory causes of asthma, but when present they may aggravate asthma which already exists.

OTHER CAUSES OF ASTHMA

In 1940 Evans and Bodman⁶⁹ developed an interesting theory — that the cause of allergic manifestations involved the absence of certain catalysts of coenzyme activity. By using an oxidation catalyst — ethylene disulfonate — they attempted to restore the deficiency. They had no objective findings to confirm their theory, and the treatment recommended — ethylene disulfonate — has been shown to be worthless.

Another concept about allergy is much more interesting. In 1936 Selye⁷⁰ presented his theory of the adaptation syndrome, which may be defined briefly as the response of the organism to stress or damage to which it is not adapted. The first or shock phase when the patient is subjected to the alarming stimulus is characterized by tachycardia, a decrease in muscular tone and body temperature and a rise and then a fall in the blood pressure and in the blood sugar. There is anuria, acidosis and a discharge of adrenaline from the adrenal medulla. With these go certain other changes, such as hemoconcentration, edema formation, leukopenia followed by leukocytosis, negative nitrogen balance and chemical changes in the blood, including an increase in nonprotein nitrogen, potassium, phosphate and globulin and a decrease in the blood chloride. The shock phase is followed by the countershock phase in which the subject begins to develop resistance to the damaging agent. There is enlargement of the adrenal cortex and a general reversal of the changes occurring in the shock phase, with an increase in production of corticoid hormones from the adrenal cortex accompanied by a decrease in urinary excretion of 17 ketosteroids. Thirdly, there is the stage of resistance, and finally the stage of exhaustion. Selye⁷¹ calls conditions in which these changes occur "diseases of adaptation" and cites as examples hypertension, nephrosclerosis, rheumatic fever, perianteritis nodosa and gastrointestinal ulcers.

This idea of Selye is pertinent to the asthma problem. There is no doubt that asthma is often a reaction to stress and strain. The only difficulty is that the objective findings, particularly the chemical changes observed in asthma, are not always the same as those described by Selye for his adaptation syndrome. The problem is being studied further.

Williams⁷² put forward the hypothesis that physical or intrinsic allergy (Menière's disease) is a disorder of the normal alarm reaction and that there is an inherited disorder of certain localized cells in which, in response to certain normal stimuli, the cells are unable to utilize the normal amount of adrenal hormones available to counteract the histamine released, or else too much histamine is released for the amount of available adrenal hormone to counteract.

* * *

It will be noted that none of the investigations reviewed above have greatly helped an understanding of the fundamental basis of allergy. Most of the chemical changes observed in allergic disorders seem to be results of these conditions rather than causes of them.

The theory that treatment with potassium improves patients with allergic disorders has not been

generally accepted, and such therapy does not seem to be of great value. When disturbances of water balance occur, they should certainly be corrected. A study of the total balances, — that is, the total intake as compared to the total output, of sodium, potassium and water in the body, — together with the use of radioactive materials, may reveal more accurately than simple blood levels any shift of these substances in the cells and tissues of the body that may occur in allergy.

Therapy with calcium or magnesium is not specific for allergic conditions and is not indicated unless an actual deficiency of these substances in allergic patients is proved. So far as blood sugar is concerned, it would be interesting to know if it is at a low level at the onset of nocturnal attacks of asthma, if this can be shown, carbohydrate feedings before retiring at night may benefit some patients. Insulin shock seems to be justified only when psychiatric factors are dominant in aggravating the symptoms.

Since the metabolism of cholesterol and fat is not well understood in the normal person, it is hard to say whether a disturbance exists in allergic patients, although this does not seem likely on the evidence so far available.

Deficiencies of ascorbic acid or niacin cannot be incriminated as causative factors in allergy. There have been few reports on the functions of the other vitamins in allergic disorders, but from what is known about these vitamins at present it does not seem likely that any of them are specifically concerned. Perhaps a new vitamin will be discovered that may turn out to be of vital importance in allergy. Meanwhile, all patients suffering from chronic diseases should be properly fed, and the diet should include adequate amounts of all the known vitamins, with extra quantities if a deficiency exists.

Finally, few of the changes occurring in the body during the alarm reaction have been found in asthma. There have been no conclusive reports, however, on the blood chloride, on the blood globulin or on nitrogen metabolism in asthma. Studies of these factors ought to reveal whether or not asthma, eczema and kindred diseases belong with Selye's "diseases of adaptation." Studies of the function of the adrenal cortex in asthma are also needed.

From this review of investigations in chemical changes in allergy, it is obvious that in any future work strict attention must be given to exact methods, techniques and controls, since the status of asthma depends on many variable factors.

CASE 33371

PRESENTATION OF CASE

First admission. A forty-three-year-old housewife entered the hospital because of generalized arthritis.

At the age of eighteen years the patient had had mild "rheumatism" in the legs, wrists and hands. Two years before entry the toes became swollen and painful, followed by similar involvement of the ankles and knees, the right knee more so than the left. The elbows, shoulders, jaws, hands and the spine then became affected at one time or another, and there had subsequently been a constant ache in the cervical spine. Occasionally, the joint symptoms were accompanied by fever. A year before entry the patient became unable to walk. She spent three months at a local hospital but obtained no relief, despite tonsillectomy and adenoidectomy. While she was there the eyes became red and lachrymose and began to ache. She could not read because of blurred vision. At the time of entry the hands, wrists and cervical spine were the source of the greatest discomfort. The aching pain was somewhat

relieved by aspirin. The patient had lost 18 pounds since the onset of the illness.

Physical examination revealed a pale, obese woman showing evidence of weight loss and moving with difficulty because of stiff joints. There were scattered telangiectases over the cheeks. The eyes showed lacrimation, photophobia, "bluish" sclerae, moderately deep ciliary injection and many vitreous opacities. There were also some healing marginal infiltrates at the nasal border of the right cornea and several small, firm, gelatinous-appearing nodules in the conjunctiva of the left eye just above the insertion of the external rectus muscle. The fundi were normal so far as could be determined through the medial haze. The neck and spine were stiff. The lungs were clear. The heart was not enlarged to percussion. A harsh, low-pitched systolic murmur was heard over the entire precordium, loudest in the aortic area. The aortic second sound was absent. There was a moderate systolic blow at the apex. The abdomen was normal. The temporomandibular joints, shoulders, elbows, wrists, fingers, knees, ankles and toes were stiff and limited in motion, with enlargement, irregularity and tenderness. The fingers were tapering and spindle shaped. Scattered, small, tender subcutaneous nodules were found over the extremities, particularly at the elbows.

The temperature was 99.8°F, the pulse 105, and the respirations 22. The blood pressure was 140 systolic, 90 diastolic.

Examination of the blood disclosed a red-cell count of 4,340,000, with a hemoglobin of 70 per cent, and a white-cell count of 7800, with 95 per cent neutrophils. The total serum protein was 8.3 gm per 100 cc, with 4.0 gm of albumin and 4.3 gm of globulin. The sedimentation rate was 1.47 mm per minute. A blood Hinton test was negative.

A Congo-red test showed 100 per cent retention of the dye in the serum. The urinary sediment contained numerous white cells but was otherwise negative. A phenolsulfonephthalein test showed 50 per cent excretion of the dye in one hour.

On x-ray examination the heart was at the upper limits of normal. The lungs were clear. There was irregular destruction of the joint surface of the majority of the metacarpal, carpal, interphalangeal and phalangeal joints. The adjacent bone was markedly decalcified. No bony fusion was apparent, but there was slight subluxation in the first metacarpophalangeal joint. The feet showed similar changes. There were areas of subchondral destruction in the elbow and knee joints. The sacroiliac joints and spine disclosed no evidence of involvement. The sinuses were normal. There was marked caries, with apical abscess formation about the first left lower molar and the first left upper molar bicuspids. An electrocardiogram was normal.

The patient did well on aspirin, mild sedation, leg casts, raw liver and general supportive measures, with gradual simultaneous improvement in both joint and ocular symptoms. A biopsy of one of the subcutaneous nodules from the right elbow was reported as showing a "rheumatic nodule, probably rheumatoid." After three months in the hospital a definite soft aortic diastolic murmur appeared, and a low-pitched late diastolic rumble was thought to be present at the apex when the patient was lying on the left side.

Another electrocardiogram showed a greater shift to the left of the electrical axis than did the previous record. The sedimentation rate was 148 mm per minute. After four months in the hospital the patient was cystoscoped because of continued pyuria. Stones were found in the left ureter, and a left ureteromeotomy was done to facilitate their passage. An intravenous pyelogram showed normal excretion of the dye bilaterally. On discharge after six and a half months in the hospital the patient had regained sufficient strength to walk 10 or 15 feet. At times she still had considerable pain in the knees and ankles. Objectively, the joints showed little change. The eyes were symptomatically improved, but the patient was unable to read because of the medial opacities.

Final admission (seven years later). After discharge the patient continued to feel much better, although the limitation of motion progressed slowly. Nevertheless, she was able to use a "walker" until one year before entry, when she had an acute exacerbation following a minor emotional upset (an altercation with a maid). Some months later several "abscessed" teeth fell out, and the right ear became painful, with perforation of the eardrum. At about the same time the ankles began to swell and five months before entry a physician noted an enlarged spleen and a slight amount of abdominal fluid. The edema and ascites gradually progressed. Three

paracenteses were performed, each productive of about 4000 cc of fluid.

Physical examination revealed massive edema from the feet to the lower chest. The pupils were slightly irregular, the right was larger than the left. Both nasal cavities were filled with dry bloody crusts. The lungs were clear, except for occasional rales at the bases. The border of the heart extended 13 cm to the left of the midsternal line in the fifth interspace. A harsh Grade III systolic murmur was heard over the entire precordium, but best over the midsternum in the third interspace. A Grade II, high-pitched diastolic murmur was loudest at the left sternal border in the third interspace. The spleen was ballotable five fingerbreadths below the costal margin. The liver edge was not felt, but by percussion it was two fingerbreadths below the costal margin. There was marked ascites. All the joints of the extremities showed progression of the arthritis, with marked limitation of motion and some subluxations.

The temperature was 99°F, the pulse 88, and the respirations 20. The blood pressure was 128 systolic, 60 diastolic.

Examination of the blood showed a red-cell count of 4,600,000, with 12.2 gm of hemoglobin, and a white-cell count of 4500, with 82 per cent neutrophils. The serum protein was 4.4 gm per 100 cc, with an albumin of 1.3 and a globulin of 3.2 gm. The nonprotein nitrogen was 79 mg, the serum cholesterol 250 mg and the cholesterol esters 178 mg per 100 cc. The corrected sedimentation rate was 185 mm per minute. A Congo-red test showed 46 per cent retention of the dye in the serum. The cephaloflocculation test was ++ in twenty-four and +++ in forty-eight hours. The thymol turbidity was 60 units. The urine was acid and had a specific gravity of 1.020. It gave a ++++ test for albumin. The sediment contained occasional hyaline casts and 15 to 20 white cells per high-power field.

An x-ray film of the chest revealed some prominence of the heart in the region of the left ventricle, with a cardiothoracic ratio of 16/31. There was a small amount of fluid in the right pleural sinus.

An electrocardiogram showed sinus rhythm. The rate was 75. The PR interval was 0.16 second, and the QRS complex 0.06. There were notched, low P waves and inverted T waves in Leads 1 and 2 and a flat T wave in Lead 3. The QRS complexes in Lead CF were normal. The T wave in Lead CF was inverted, and that in Lead CF, slightly inverted.

Despite the administration of Mercupurin, the patient excreted less than 500 cc. of urine a day. An abdominal paracentesis produced 4000 cc of cloudy-yellow fluid, with a specific gravity of 1.006. It contained many diplococci and 250 cells per cubic millimeter, 90 per cent of which were mononuclear forms. The patient gradually became hyperneic,

lapsed into coma and died on the ninth hospital day

DIFFERENTIAL DIAGNOSIS

DR ALFRED O LUDWIG There seems to be no doubt that this woman suffered from severe, progressive rheumatoid arthritis, which had persisted for a number of years, in fact since the age of eighteen. The particular points of interest in this case are the various complications that accompanied the disease. At the onset of the illness, the history indicated that she had the exacerbations and remissions that are common in rheumatoid arthritis in the early stages. Such episodes are frequent until the disease becomes chronic, on the other hand, it may become chronic from the start.

It is of particular interest that the patient had some lesions in the eyes. From the description given I suspect that these were due to episcleritis, which frequently occurs as a complication of rheumatoid arthritis. I believe that the pathologic picture was that of a rheumatoid nodule in this area. Another ocular complication of rheumatoid arthritis is iritis, of which there was no evidence in this case.

The physical examination at the first entry was characteristic of generalized and severe rheumatoid arthritis. It is interesting that at the examination on the first admission there was no aortic diastolic murmur — only a harsh, low-pitched, systolic murmur, which I am inclined to interpret as important clinically and about which I shall say more later.

Tender subcutaneous nodules are common in rheumatoid arthritis and occur most frequently over the elbows. They are similar to those found in rheumatic fever. They may also be found over the knees, over the lateral surfaces of the ulna and occasionally in other places. I believe that they are present in about 20 per cent of cases of rheumatoid arthritis. Their pathology differs somewhat from that seen in the nodules of rheumatic fever.

The temperature, pulse and respirations do not help us much. There was a slight degree of anemia at that time. It is significant that the total protein was increased to 8.3 gm per 100 cc, and that there was an increase of the globulin fraction to 4.3 gm. I might say here that hyperproteinemia and hyperglobulinemia are not unusual findings in rheumatoid arthritis. I cannot explain why this occurs. It bears some relation to the rapid sedimentation rate seen in certain cases, although it does not explain entirely the increased sedimentation rate. Occasionally, one sees the increased globulin reflected in the spinal fluid as well, and in such cases a strongly positive gold-sol curve of the paretic type may also be found. The blood Hinton and the spinal-fluid Wassermann reactions in such cases are negative. The total protein may also be increased in the spinal fluid as a reflection of this change in the blood. This is particularly important in patients in whom the

sacroiliac joints are involved, and such lesions may be confused with ruptured intervertebral disks.

At that time there was no abnormality in the Congo-red test. Whether or not the presence of white cells in the urine was significant, I do not know. We are not told whether this was a catheterized specimen. The phenolsulfonephthalein test was normal.

It is interesting that after three months of hospitalization a definite aortic diastolic murmur appeared. Someone thought that he heard a low-pitched, late, diastolic rumble at the apex, which suggests that there was definite valvular involvement of the heart, with lesions of the aortic and mitral valves. What does that mean in a case such as this? Here is a patient with apparently definite rheumatoid arthritis involving most of the joints who developed findings in the heart that are consistent with rheumatic heart disease, or at least are those that one usually associates with it. A number of cases have been described in which heart lesions of this sort occurred coincident with chronic rheumatoid arthritis.* These lesions are predominantly located on the aortic valves. We also have seen such cases in this hospital. I do not know whether or not the histology of this type of endocarditis differs from that found in rheumatic fever.

It is also interesting that the electrocardiogram showed a greater left-axis deviation than previously. The sedimentation rate, of course, was greatly elevated, the normal being 0.35 mm per minute.

It was thought necessary to cystoscope this patient because of continued pyuria. Apparently, the white cells previously reported in the urine were important. Stones were found on that examination, which raises the question how the stones got into the left ureter. Two possibilities suggest themselves. In the first place, this patient, like all patients with severe chronic rheumatoid arthritis, had a great deal of decalcification and, therefore, undoubtedly excreted much more calcium in the urine than normally. Furthermore, she had a urinary infection. Whether the infection preceded and therefore contributed to the stones or whether it followed the stones, I do not know. At that time she still did not show any decrease in renal function. It is obvious that she had not really made any great clinical progress after the long period of hospitalization.

At the second admission the important points were the appearance of edema of the ankles, an enlarged spleen and the presence of abdominal fluid. From that time on, both edema and ascites increased steadily to the point where three abdominal paracenteses had to be done. Examination confirmed this finding of massive edema from the chest down. I cannot believe that the irregularity of the pupil

*Baggenstoss, A. H., and Rosenberg, E. F. Cardiac lesions associated with chronic infectious arthritis. *Arch Int Med* 67:241-258, 1941.

was important, except that it may have been evidence of a previous intus. The heart border extended 13 cm. to the left. That is significant, but one cannot be certain that the enlargement was not apparent and due to increased abdominal fluid, which pushed the heart up and out. The murmurs had definitely changed. There was a Grade III systolic murmur over the precordium, heard best over the mediastinum, and a Grade II, high-pitched aortic diastolic murmur, loudest at the left sternal border, the position in which one usually expects to hear aortic murmurs best. Both the spleen and the liver appeared to be considerably enlarged. The joint lesions had shown continued progression.

The laboratory findings are of some importance. There was still a slight degree of anemia. This and the diminution of the white-cell count occur in rheumatoid arthritis. The leukopenia was part of what has been described as Felty's syndrome—a clinical picture consisting of leukopenia, splenomegaly and lymphadenopathy in association with rheumatoid arthritis. The serum protein was below normal, but there was still a marked increase in the amount of globulin, with reversal of the albumin-globulin ratio. The nonprotein nitrogen was elevated to more than twice the normal, and there was also an increase in the cholesterol and cholesterol esters. The sedimentation rate was as high as before. I do not believe that the Congo-red test was significant. The cephalin-flocculation and the thymol-turbidity tests, as well as the increased globulin level in the serum, are used to aid in the diagnosis of decreased liver function. The urinary findings improved. There was marked albuminuria, with presumably a good specific gravity—if the patient could concentrate to 1 020, she had not lost much renal function.

I shall have to ask a cardiologist to interpret the electrocardiogram.

The final course showed increasing oliguria. Abdominal paracenteses continued to produce large amounts of fluid. We are told that the fluid became infected. Diplococci and leukocytes were found in it, so that the patient was developing or had already developed a low-grade peritonitis, presumably due to a pneumococcus. This is not infrequent with nephrosis and is not rare as the terminal event with this complication. The hyperpnea I explain on the basis of acidosis from increasing renal failure.

There are several perplexing points about the case. What other possibilities might account for these complications? We have a good deal of evidence that this patient had rather extensive amyloid infiltration, including an amyloid nephrosis. The renal findings were consistent with it, as was the Congo-red test and the enlargement of the liver and spleen. There are other things, however, that may have been implicated. The patient may have had a sufficient degree of impaired liver function with cirrhosis to account for the ascites, although I

do not believe from the information at hand that one is justified in drawing that conclusion.

Finally, is it necessary to assume any serious degree of heart failure to account for the production of ascites? I do not believe from the clinical findings that this is so. Nor is there sufficient evidence to say that there was impairment of the venous return to the heart. One might consider a tricuspid lesion, of which I cannot see any evidence. So far as the kidneys are concerned, one cannot forget that the patient had renal infection, pyelitis and pyelonephritis, which may also have contributed to the eventual breakdown of renal function. Before we go farther, it would be wise to see if the x-ray film will help and also to ask the cardiologists to interpret the electrocardiographic findings.

DR STANLEY M. WYMAN Unfortunately, the films of the first examination are no longer available. This film of the chest was taken in the supine position, so that accurate measurement of the heart is impossible. The right leaf of the diaphragm is elevated more than usual. The lung fields are clear. The heart shadow may be prominent toward the left. The changes in the hand are those of severe osteoporosis, with loss of subchondral bone in the carpal bones and in the terminal portions of several of the phalanges.

DR LUDWIG These x-ray films show extensive destruction around the joints.

DR EDWARD F. BLAND The electrocardiogram shows a digitalis effect on the ST intervals and perhaps evidence of slight left ventricular strain.

DR LUDWIG I should be satisfied to leave the diagnosis as extensive, severe chronic rheumatoid arthritis complicated by serositis and by a heart lesion, the nature of which I am not certain. I think it will be demonstrated that there was involvement of both the aortic and the mitral valves and, finally, that there was extensive amyloid infiltration secondary to the rheumatoid arthritis and involving primarily the spleen, liver and kidneys. I also predict that there was some degree of pyelonephritis.

DR BLAND We saw this patient repeatedly in 1939 and 1940. We were especially interested at that time in a group of patients with rheumatoid arthritis who also had valvular heart disease. One of this group had a high degree of nonspecific aortitis and aortic regurgitation, which Dr Mallory was not quite willing to classify at autopsy. This patient, however, does not seem to fit this special group. The cardiac signs began with a systolic murmur, and it was not until considerably later that we also recognized an aortic diastolic murmur. Aortic-valve disease, with predominant stenosis acquired at a relatively early age, always suggests the possibility that an inflammatory lesion has been superimposed on a bicuspid aortic valve. I should like to throw that possibility in. I doubt if she had mitral disease except on a statistical basis.

DR LUDWIG On the basis of the type of heart disease that we see in rheumatoid arthritis?

lapsed into coma and died on the ninth hospital day

DIFFERENTIAL DIAGNOSIS

DR ALFRED O LUDWIG There seems to be no doubt that this woman suffered from severe, progressive rheumatoid arthritis, which had persisted for a number of years, in fact since the age of eighteen. The particular points of interest in this case are the various complications that accompanied the disease. At the onset of the illness, the history indicated that she had the exacerbations and remissions that are common in rheumatoid arthritis in the early stages. Such episodes are frequent until the disease becomes chronic, on the other hand, it may become chronic from the start.

It is of particular interest that the patient had some lesions in the eyes. From the description given I suspect that these were due to episcleritis, which frequently occurs as a complication of rheumatoid arthritis. I believe that the pathologic picture was that of a rheumatoid nodule in this area. Another ocular complication of rheumatoid arthritis is iritis, of which there was no evidence in this case.

The physical examination at the first entry was characteristic of generalized and severe rheumatoid arthritis. It is interesting that at the examination on the first admission there was no aortic diastolic murmur — only a harsh, low-pitched, systolic murmur, which I am inclined to interpret as important clinically and about which I shall say more later.

Tender subcutaneous nodules are common in rheumatoid arthritis and occur most frequently over the elbows. They are similar to those found in rheumatic fever. They may also be found over the knees, over the lateral surfaces of the ulna and occasionally in other places. I believe that they are present in about 20 per cent of cases of rheumatoid arthritis. Their pathology differs somewhat from that seen in the nodules of rheumatic fever.

The temperature, pulse and respirations do not help us much. There was a slight degree of anemia at that time. It is significant that the total protein was increased to 8.3 gm per 100 cc, and that there was an increase of the globulin fraction to 4.3 gm. I might say here that hyperproteinemia and hyperglobulinemia are not unusual findings in rheumatoid arthritis. I cannot explain why this occurs. It bears some relation to the rapid sedimentation rate seen in certain cases, although it does not explain entirely the increased sedimentation rate. Occasionally, one sees the increased globulin reflected in the spinal fluid as well, and in such cases a strongly positive gold-sol curve of the paretic type may also be found. The blood Hinton and the spinal-fluid Wassermann reactions in such cases are negative. The total protein may also be increased in the spinal fluid as a reflection of this change in the blood. This is particularly important in patients in whom the

sacroiliac joints are involved, and such lesions may be confused with ruptured intervertebral disks.

At that time there was no abnormality in the Congo-red test. Whether or not the presence of white cells in the urine was significant, I do not know. We are not told whether this was a catheterized specimen. The phenolsulfonephthalein test was normal.

It is interesting that after three months of hospitalization a definite aortic diastolic murmur appeared. Someone thought that he heard a low pitched, late, diastolic rumble at the apex, which suggests that there was definite valvular involvement of the heart, with lesions of the aortic and mitral valves. What does that mean in a case such as this? Here is a patient with apparently definite rheumatoid arthritis involving most of the joints who developed findings in the heart that are consistent with rheumatic heart disease, or at least are those that one usually associates with it. A number of cases have been described in which heart lesions of this sort occurred coincident with chronic rheumatoid arthritis.* These lesions are predominantly located on the aortic valves. We also have seen such cases in this hospital. I do not know whether or not the histology of this type of endocarditis differs from that found in rheumatic fever.

It is also interesting that the electrocardiogram showed a greater left-axis deviation than previously. The sedimentation rate, of course, was greatly elevated, the normal being 0.35 mm per minute.

It was thought necessary to cystoscope this patient because of continued pyuria. Apparently, the white cells previously reported in the urine were important. Stones were found on that examination, which raises the question how the stones got into the left ureter. Two possibilities suggest themselves. In the first place, this patient, like all patients with severe chronic rheumatoid arthritis, had a great deal of decalcification and, therefore, undoubtedly excreted much more calcium in the urine than normally. Furthermore, she had a urinary infection. Whether the infection preceded and therefore contributed to the stones or whether it followed the stones, I do not know. At that time she still did not show any decrease in renal function. It is obvious that she had not really made any great clinical progress after the long period of hospitalization.

At the second admission the important points were the appearance of edema of the ankles, an enlarged spleen and the presence of abdominal fluid. From that time on, both edema and ascites increased steadily to the point where three abdominal paracenteses had to be done. Examination confirmed this finding of massive edema from the chest down. I cannot believe that the irregularity of the pupil

*Baggenstoss, A. H., and Rosenberg, E. F. Cardiac lesions associated with chronic infectious arthritis. *Arch. Int. Med.* 67:241-258, 1941.

brought to a steady level of 123 to 143 mg. The hemoglobin, white-cell count, differential count, serum nonprotein nitrogen, total protein and carbon dioxide were within normal limits. Repeated sputum examinations were negative for tubercle bacilli. A chest film revealed an area of increased density extending upward from the left lung root into the apical division of the left upper lobe. There was a 5-cm., ragged cavity within it that seemed to have a fluid level. The left leaf of the diaphragm was elevated but moved freely. There was a small amount of fluid in the left pleural sinus. The left upper lobe was not much reduced in size. The right lung was clear. Two bronchoscopic examinations disclosed constriction of the left upper-lobe bronchus, but both biopsies and smears were negative for carcinoma.

The patient was discharged on the eighteenth day.

Second admission (one month later). The patient was readmitted with fever, chills and dyspnea. In the interval he had felt reasonably well except for persistent cough and expectoration of about a cupful of sputum a day, which was blood streaked on occasions. He continued to have pain off and on in the left anterior portion of the chest, along with some substernal pressure, but this was not related to exercise, cough or deep respiration. There was no appreciable weight loss. One day before admission he had dyspnea, chills and fever.

Physical examination showed no change from those on the first admission.

The temperature was 103°F, the pulse 100 and the respirations 23, but these were readily controlled with penicillin therapy.

Examination of the blood revealed a white-cell count that varied from 14,800 to 10,000. The fasting blood sugar was 121 to 139 mg per 100 cc. The blood chemical findings were otherwise normal.

X-ray examination showed some increase in the size of the cavity in the left upper lobe and some elevation of the left leaf of the diaphragm.

A third bronchoscopy showed only constriction of the left upper-lobe bronchus, the biopsy was negative for carcinoma.

An operation was performed on the twenty-third hospital day.

DIFFERENTIAL DIAGNOSIS

Dr. LOWREY F. DAVENPORT. Since most of the findings, including the sputum examination and bronchoscopy, were negative, our chief reliance is on the serial x-ray films, and I should like to request that they be shown.

Dr. STANLEY M. WYMAN. The cavity discussed lies in the apex of the left upper lobe medially. It can be distinctly seen in the lateral view. There is some density throughout the apical portion of the left upper lobe. Elevation of the left leaf of the diaphragm is well seen in the entire series. A film taken twelve days later shows a definite fluid level

in the base of the cavity, but no other essential change. In a film taken a month later the cavity appears to be considerably larger, with again a small fluid level in its base. A film taken two weeks later shows no definite change except for some decrease in the reaction around the ring shadow. There is, however, one thing to add to this report — that is, what appears to be a small nodule in the right lower-lung field. This is present only on the film taken at the last examination.

Dr. DAVENPORT. Two months prior to the first admission this fifty-six-year-old man presented symptoms of a respiratory infection — fever, cough and sputum. The subsequent course on the two hospital admissions and the serial x-ray films suggest a destructive process involving the left upper lobe. We are faced, as we always are in these cases, with the problem of trying to differentiate simple lung abscess and abscess complicated by tumor or some chronic type of inflammatory process, such as tuberculosis. I believe that it is to these three possibilities only that we should give our serious attention.

Confusing things about symptomatology often arise now that the antibiotics, such as penicillin, have become available. We have often been misled by the thought that a definite — sometimes a dramatic — response in temperature, white-cell count and the site of the x-ray shadow following penicillin are evidence against the possibility of an underlying tumor. We should remember that if there is bronchial obstruction with underlying suppuration the inflammatory reaction secondary to the bronchial obstruction can be influenced markedly by penicillin and the various sulfonamides. The facts that the original episode of so-called "grippe" responded to treatment and that the symptoms of inflammation at the time of the first admission responded to penicillin therapy are of no help in reassuring us regarding the inflammatory nature of the process.

Always, when a patient presents glycosuria, as in the case under discussion, and an elevated blood sugar, we must be on the lookout for the bizarre forms of tuberculosis. Tuberculosis in a diabetic patient is notoriously difficult to diagnose in some of the early stages because it does not behave according to the usual pattern. It starts out with a fulminating process, with inflammation and an acute exudative process similar to acute lobar pneumonia, and may excavate readily. But in a patient in the hospital for as long a period as this patient was, with repeated sputum examinations and a cavity as large as this, in whom no tubercle bacilli have been found in repeated searches, it is reasonable to exclude tuberculosis. Occasionally in tuberculosis sanatoriums we see cavities with negative sputum on persistent examination. Most of them are observed in cases of chronic productive tuberculosis in which the cavity has epithelialized. I cannot conceive of tuberculosis in such a rapidly destruc-

tive process as this without innumerable tubercle bacilli in the sputum

Could this have been a simple lung abscess that had been held more or less in abeyance by sulfonamide therapy and antibiotics? There are several points in the history against the possibility that this was the type of abscess that follows tooth extraction, foreign body or toxemia. The rapidity of excavation and the type of sputum were much against it. Also, bronchoscopy gave chiefly negative evidence but one bit of helpful data although there was no evidence of growth in the bronchus, constriction of the left upper-lobe bronchus was noted on both occasions. If this had been tuberculosis of a rapid fulminating nature, constriction on a tuberculous basis could not have taken place so quickly. Nor, in simple lung abscess, would one expect constriction, even though the bronchoscopic findings were essentially negative.

The report on two occasions that there was constriction of the bronchus in the left upper lobe makes me lean definitely to the diagnosis of primary bronchiogenic cancer, with bronchial obstruction, suppuration and excavation. That brings us up to the method of handling these cases. Before the days of chemotherapy when the chest was opened with fear, and before pneumonectomy and lobectomy were being done, we studied some of these patients overzealously, trying to establish the diagnosis between a simple lung abscess, tumor and inflammatory, nontuberculous and tuberculous processes. We now believe that it is wise to excise a localized destructive process in the lung, whether benign or malignant, suppurative or tuberculous, in the absence of definite evidence of involvement elsewhere. As is well known, more and more frequently we are going ahead in cases of localized tuberculosis and picking primary resection as the treatment of choice. Since I have seen these x-ray films and had the nodule called to my attention, I am somewhat more hesitant about recommending operation because I lean strongly to a malignant process, and if this was a malignant process, with a metastatic nodule already formed at the right base, operation, of course, was hopeless from the standpoint of effecting a cure. This nodule also raises the bare possibility that the left upper-lobe process was

not a primary bronchiogenic carcinoma but a metastatic process. I think that that is most unlikely because metastatic nodules rarely cause obstruction and ordinarily do not break down and excavate as the lesion did in this case.

I should have advised operation on the first admission with the tentative working diagnosis of primary bronchiogenic cancer, with secondary excavation due to a blocking process and suppuration.

CLINICAL DIAGNOSIS

Lung abscess (? carcinoma)

DR DAVENPORT'S DIAGNOSIS

Carcinoma of lung

ANATOMICAL DIAGNOSIS

Squamous-cell carcinoma of lung

PATHOLOGICAL DISCUSSION

DR LAMAR SOUTTER. When the chest was entered, innumerable dense adhesions were found over the entire lung. These were freed, and the abscess entered at the apex of the lung, where it was adherent to the upper part of the chest anteriorly. The abscess extended down along the mediastinal vessels and the arch of the aorta into the posterior portion of the chest. The septum between the upper and lower lobes could not be dissected clear because the abscess extended across it. It was obvious that a pneumonectomy would be necessary. Because of the extensive infection along the mediastinum and the large hilar nodes, it was thought that this procedure would be very hazardous, hence, the chest was closed. A catheter was inserted for drainage.

DR BENJAMIN CASTLEMAN. A biopsy of the abscess wall showed a well differentiated squamous-cell carcinoma, with marked epithelial pearls and keratinization. This abscess was broken-down tumor rather than a true non-neoplastic abscess beyond an obstructing tumor, which not infrequently occurs in the lung. In this latter group of cases we have seen metastatic cerebral abscesses without metastases from the cancer itself.

A PHYSICIAN. What was the eventual course?

DR CASTLEMAN. The patient is still on the ward and receiving x-ray treatment. It is planned to achieve a total dosage of 3000r.

TETANUS IN THE UNITED STATES ARMY IN WORLD WAR II

EARLY last year Boyd¹ reviewed the British experiences with tetanus in the African and European theaters of operation, and his report has already been commented on in these columns.² Active immunization as employed at first in the British Army consisted of two doses of toxoid, 1 cc each, about six weeks apart. Later a third dose was included in the initial course. An annual booster dose of 1 cc was also given, and in addition, a single dose of 3000 units of tetanus antitoxin was administered immediately after a wound was sustained in those who had been actively immunized. The same amount of antitoxin was given at weekly intervals to those who had not been immunized. Boyd concluded from his data that tetanus

was not entirely prevented by active immunization, since 22 cases occurred in persons who had been actively immunized. Furthermore, although the mortality from the disease was significantly lower in those actively immunized patients who had also received prophylactic antitoxin, in patients who were actively immunized and had not received antitoxin the mortality was not below average. He therefore concluded that the failures were due to a low level of antitoxin at the time of wounding and that this was best remedied by giving antitoxin during the period while the patient was making his own, the best effects being obtained from the early administration of antitoxin.

Corresponding data from the United States Army are now available and are of particular interest because of the differences in the methods employed and in the results attained.³ In the Army, fluid, not alum-precipitated, tetanus toxoid has been used as an immunizing agent for the prevention of tetanus since 1941. All military personnel received a series of three subcutaneous injections of 1 cc at intervals of three weeks. A routine stimulating injection of 1 cc of toxoid was administered one year after the initial series, and an emergency stimulating dose was given on the incurrence of wounds, severe burns or other injuries that might result in tetanus. In addition, a stimulating dose was also given at the time of manipulation of old wounds that were considered as potentially contaminated by *Clostridium tetani*. Before September, 1944, an additional stimulating dose of 1 cc was given to all persons departing for a theater of operations more than six months after the basic series or the routine stimulating dose, after that time data indicating that this precaution was not necessary had accumulated. At present no further toxoid is given after the routine stimulating dose unless the individual sustains an injury that might result in tetanus, at which time the emergency stimulating dose of 1 cc of toxoid is administered. Tetanus antitoxin is reserved for the treatment of clinical tetanus and for passive immunization of injured persons in whom there is no evidence of previous administration of toxoid.

Studies were made to determine the levels of antitoxin during the various stages in these im-

munization procedures. It was found that one week after the third injection of the initial series, all specimens contained at least 0.1 unit of antitoxin per cubic centimeter of serum and some contained much more. Since the amount of circulating antitoxin required for protection against tetanus is estimated to be between 0.01 and 0.20 unit per cubic centimeter of serum, it was considered that there was adequate protection immediately after completion of the initial series and that there was no need for prophylactic antitoxin. To determine how long a basic active immunity persists that is sufficient to allow for adequate response to a stimulating dose, a group of persons was studied one year after the completion of the basic course of toxoid. Before administration of the stimulating dose relatively small quantities of circulating antitoxin were present, but one week after this stimulating dose, levels of 0.3 unit or more per cubic centimeter were reached in almost every subject. Comparable results had previously been obtained by Mueller and his associates.⁴ In immunized persons who had not received injections of toxoid over a period of from two to five years, only about 10 per cent failed to develop a level of antitoxin that was adequate for protection and the protective levels were produced within a week in all cases. It was therefore considered wise to continue the administration of emergency stimulating doses of toxoid following injury, and it was also thought that an adequate response would then occur within the usual incubation period of tetanus.

Two types of reactions to the toxoid were observed. The first was apparently nonspecific in nature and was manifested by symptoms similar to those that occur after typhoid vaccination, that is, local soreness at the site of injection, headache, general malaise and occasionally chills and fever. These local and general reactions were much less frequent and less severe than those following the injection of typhoid vaccine. The second type of reaction was characterized by the appearance—within thirty minutes—of flushing and itching of the skin or of frank urticaria and occasionally edema of the lips and eyelids. Edema of the glottis and respiratory difficulties were rare. In about 85 per cent of the cases these reactions occurred after the

second or third dose, suggesting the production of a hypersensitive state by a previous dose. The majority of the latter type of reactions occurred in the tetanus immunization program, and it was soon recognized that they were a manifestation of sensitivity to some constituent of the toxoid that toxoids containing certain types of peptones were the worst offenders. Cessation of the use of toxoids containing these peptones was followed by a decrease in the frequency of these reactions from 63 per 100,000 injections to less than 2. The incidence of reactions resulting from the use of toxoids now available is extremely low, and reactions from initial injections of these materials are almost nonexistent.

Throughout the entire war period only 12 cases of tetanus occurred among Army personnel, although some other cases may have been overlooked. It also occurred among wounded soldiers who fell into the hands of the enemy. The 12 recognized cases included 4 that resulted from injuries sustained while on active duty. Interestingly enough, only 6 of 12 cases occurred in those who had received full prophylactic doses, including the emergency stimulating dose of toxoid after injury.

A comparison with the previous experience of the Army is of interest. In World War I, there were 70 cases of tetanus among approximately 10 million admissions for wounds and injuries, an incidence of 13.4 per 100,000. In the period between the two world wars there was a similar total number of admissions, with 14 cases of tetanus or 2.4 per 100,000. In World War II there were about three million admissions for wounds and injuries with a tetanus case rate of only 0.44 per 100. Furthermore, a considerable number of cases of serum sickness were undoubtedly prevented thereby the avoidance of prophylactic antitoxin in the latter period.

The incidence among enemy forces is not entirely known, but from the data that are available American experience stands out most favorably. For example, it has been reported that there were some 10 cases per 100,000 wounded in the Japanese Army and Navy from 1940 through 1944, a figure comparable with that which occurred among American troops in World War I. Among civilians

ilities during the Manila operations there were almost 500 cases. A report from Europe states that during the Normandy invasion unimmunized German ground forces suffered over 80 cases of tetanus but that there were no such cases in the immunized *Luftwaffe*. There were also 53 cases among American-held German prisoners of war in England during a single month in the latter part of 1944.

The Army report also reviews the civilian mortality from tetanus in the United States and draws attention to the high mortality rate, especially during infancy and early childhood. The civilian mortality rate in young adults during the period of 1936-1938 was calculated as being about twenty times as high as the Army rate in World War II.

From experience gained in the use of tetanus toxoid in the war there is no doubt regarding the efficacy of this procedure for the prevention of tetanus. In military practice reliance was not placed on a continuing state of immunity following immunization, instead, advantage was taken of the rapid rise in blood antitoxin levels that occurs soon after the administration of a stimulating dose of toxoid. Although tetanus is not frequently encountered in civilian practice, it is sufficiently important to warrant active immunization of children and of adults whose activities might lead to injuries potentially infected with *Cl. tetani*. Such persons, when immunized, should be furnished with a record of the procedure so that physicians subsequently treating their injuries may know that the administration of toxoid and not of antitoxin is the treatment of choice.

The Army experience gives no indication concerning the relative efficacy of alum-precipitated toxoid. For children, that agent is thought to be quite satisfactory, particularly since it lends itself well to combination with other antigens, such as diphtheria toxoid. Fluid toxoid, because of its more rapid absorption is considered to be the agent of choice for the booster dose, but there is no good indication that the alum-precipitated material is not just as effective under these circumstances.

In general, it is probably a reasonably safe procedure to give toxoid rather than antitoxin prophylactically to an ex-serviceman who sustains an injury if he states that he was in service for at least a year

subsequent to Pearl Harbor and that he received all the routine immunizations administered in his organization. Such a military experience would almost certainly indicate that he had received at least the basic course and would therefore be expected to respond satisfactorily to a stimulating dose of tetanus toxoid.

GREATER BOSTON NURSING COUNCIL

THERE has been a succession of birthday observances over the years—tercentenaries, sesquicentennials and centenaries—as the settlements and the institutions of our country have paused at various chronologic vantage points to view the achievements of their past. A local youngster now calls attention to the accomplishments of its first decade of life.

The Greater Boston Nursing Council, although organized as the Community Nursing Council on November 17, 1937, had its actual beginning seventeen years earlier in the Committee on Public Health Nursing of the Boston Health League—that uncannily ubiquitous and inclusive organization that, like the news weekly, sees all and hears all. Interested in being sure that all groups in the community had adequate nursing care, the Committee on Public Health Nursing appointed a committee to ascertain the nursing needs in Boston and the community resources to meet these needs. As a result of the recommendations of this committee the Community Nursing Council came into being, becoming in 1942 the Greater Boston Nursing Council for War Service and in 1946 simply the Greater Boston Nursing Council, under which name it now functions.

The activities and the accomplishments of the Nursing Council have already been many as it arrives at its tenth birthday. In the legislative field, with the Massachusetts State Nurses Association, it has been active in promoting legislation to

make mandatory the registration of nurses and to regulate subsidiary workers In 1942 and 1943 it recruited graduate nurses for the staffing of the proposed Army hotel hospitals, which fortunately were not needed, it did the important work of classifying nurses under the Procurement and Assignment Service of the War Manpower Commission For nearly five years it has been active in recruiting students for the Greater Boston nursing schools It has undertaken a number of surveys of nursing services, it has studied nurses' salaries, it is currently sponsoring a committee to consider the matter of experience and observation in public-health nursing for graduate and undergraduate students

The Nursing Council will continue to have ample opportunity to make its services felt, for the difficulties of supply and demand and the costs in the nursing field continue in an acute phase We are fortunate in having such an organization ready to do its share in the study of these problems

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

COMMUNICABLE DISEASES IN MASSACHUSETTS FOR JULY, 1947

COMMENT

Diseases above the seven-year median were chicken pox, diphtheria, dog bite, malaria, lobar pneumonia, poliomyelitis, salmonellosis and undulant fever Chicken pox was at the highest level in the records of the Department. Diphtheria declined again, there were 20 cases in July compared with 38 and 37 for May and June, respectively

Poliomyelitis showed the usual seasonal increase, with 21 cases in July whereas only 9 were reported for the preceding six months, 11 were reported in July, 1946 Diseases below the seven-year median were bacillary dysentery, German measles, gonorrhea, measles, meningococcal and Pfeiffer-bacillus meningitis, mumps, scarlet fever, syphilis, tuberculosis, typhoid fever and whooping cough. Measles reached the lowest level since 1935, and scarlet fever the lowest in the records of the Department

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Billerica, 1, Boston, 10; Chelsea, 1, Duxbury, 1, Foxboro, 1, Lynn, 1, Revere, 1, Somerville, 1, Winchendon, 1, total, 20
Dysentery, bacillary, was reported from Worcester (State Hospital), 11, total, 11
Encephalitis, infectious, was reported from Dover, 1, total, 1
Lymphocytic choriomeningitis was reported from Quincy, 1, total, 1
Malaria was reported from Barnstable, 1, Boston, 3, Cambridge, 1, Everett, 1, Greenfield, 1, Holbrook, 1, Lynn, 1, Nantucket, 1, New Bedford, 1, North Andover, 1, Waltham, 1, Williamstown, 1, Worcester, 1, total, 15
Meningitis, meningococcal, was reported from Boston, 2 Framingham, 1, Lowell, 1, Malden, 1, Montague, 1, Quincy 1, Waltham, 1, total, 8
Meningitis, Pfeiffer-bacillus, was reported from West Springfield, 1, total, 1
Meningitis, pneumococcal, was reported from Cambridge 1, Leominster, 1, total, 2
Meningitis, undetermined, was reported from Norwood, 1 Taunton, 1, Ware, 1, total, 3
Rocky Mountain spotted fever was reported from Chatham, 1, Dennis, 1, Worcester, 1, total, 3
Salmonellosis was reported from Boston, 3, Cambridge, Lawrence, 2, Waltham, 1, Wellesley, 1, Worcester, total, 13
Septic sore throat was reported from Boston, 1, Nor Brookfield, 2, total, 3
Tetanus was reported from Acton, 1, Attleboro, 1, Hopkinton, 1, Pittsfield, 1, total, 4
Trichinosis was reported from Adams, 1, Boston, Fitchburg, 3, total, 5
Tularemia was reported from Bourne, 2, total, 2
Typhoid fever was reported from Somerset, 1, total, 1
Undulant fever was reported from Ashburnham, Bolton, 1, Holbrook, 1, Warren, 1, Worcester, 2, total, 6

MISCELLANY

BOSTON UNIVERSITY APPOINTMENTS

Dr Jacob W Stutzman, a member of the department physiology at the University of Wisconsin and for the two years assistant professor of physiology at that institution, has been appointed associate professor of pharmacology at Boston University School of Medicine
Dr Sidney Licht, chief of medical rehabilitation and physical medicine for the Veterans Administration in New England, has been appointed a lecturer in physical medicine Boston University School of Medicine Dr Licht, a resident of Cambridge, formerly taught at Columbia University at New York University

CORRESPONDENCE

VACCINATION AGAINST RUBELLA

To the Editor I have read the comprehensive and critical review of rubella by Dr Wesselhoeft, which appeared in June 19 and 26 issues of the Journal, with great interest The recent knowledge of the serious effect on the fetus of this disease is contracted by the mother early in pregnancy poses new and serious problems from the viewpoint of the health officer Dr Wesselhoeft ably discusses the problems of prevention and discards as potentially too dangerous any plan to relax further our isolation practices or to

late children with rubella virus at an appropriate age. It is my conviction that the practice of inoculation presents less danger of infection of pregnant mothers than the risk that they now run of contracting the disease from contact with unknown and unsuspected cases during epidemics.

German measles is in its own right perhaps the mildest of the acute epidemic diseases and complications, as Dr. Wesselboeck asserts, are rare. Assuming that techniques of artificial inoculation can be worked out to reproduce the disease in its natural or even a milder form, the danger to the child will be no greater than the present risk or even than the present practice of vaccination against smallpox. Inoculation could be limited to girls but might better include all children. The time and conditions under which the child would be given rubella in private practice could be selected with regard to the known absence of pregnancy in the mother of the family. With pre-school children knowing the incubation period and the duration of the communicable state, isolation would be relatively easy and reliable. The argument that immunity is not always permanent is valid but experience shows that second attacks are extremely rare. This practice would protect the next and succeeding generations from the occasional, but dreadful tragedy of infecting on their unborn offspring the infirmities of prenatal rubella, as well as saving the mother from the risk of miscarriage.

The proposed program cannot be approached lightly or launched without most careful consideration of all possible contingencies. Our knowledge of artificial inoculation is meager. It should be experimented with under carefully controlled conditions in institutions to learn the best means of introducing the virus, the time and duration of the period of communicability and other pertinent details.

Whether adolescent and adult women who have no known history of rubella might be safely inoculated is another question that deserves consideration. With absolute knowledge of the fact that pregnancy does not exist, the proposal does not seem unreasonable.

Although mumps presents an entirely different problem, it may be worthwhile in passing to propose that we encourage exposure of young children to this disease or practice artificial inoculation. Its consequences in preadolescents are practically nil and complications are exceedingly rare whereas later in life orchitis in the male may be a serious affair.

I realize that the above proposals are radical and unconventional. As one who has spent much of his life in teaching and in practicing as a health officer, the prevention of epidemic diseases it may seem literal heresy. Yet I have observed the futility of our best efforts in attempting to control the acute epidemic diseases of childhood by isolation and quarantine alone. Rubella outbreaks appear spread and run their course in spite of our efforts. Now that we are confronted with a hitherto unsuspected danger to life and health from this disease, even if only rarely when we have the simultaneous occurrence of early pregnancy and rubella, I believe that the public health profession should study every possibility to prevent this event. The above proposal is at least worth further study and consideration.

C. M. HILLIARD

Simmons College
Boston

* * *

Professor Hilliard's letter was referred to Dr. Wesselboeck, whose reply is as follows:

To the Editor: The suggestion contained in Professor Hilliard's communication is a commendation devoutly to be wished but there are difficulties in bringing it about which were presented in my progress review on rubella. It is not an easy matter to cultivate the virus of rubella and furthermore, the inoculation of such material does not ensure a successful take. Until a more successful method of cultivation of the virus is achieved than has been accomplished up to the present, inoculation cannot be considered a practical procedure.

I am heartily in agreement with Professor Hilliard that every effort should be made to perfect a satisfactory vaccine against rubella. Without such a vaccine, it is well to keep in mind the problems that I attempted to set forth under the heading "Prevention."

CONRAD WESSELBOECK, M.D.

Boston

BOOK REVIEWS

Treponematosis. By Ellis Herndon Hudson. 4th paper, 122 pp. New York: Oxford University Press, 1946. Reprinted from *Oxford Medicine*.

This book constitutes a new and important interpretation of available evidence regarding the relation between the various maladies produced by treponemes. The evidence considered embraces the historical, clinical, pathological, immunologic and epidemiologic aspects of the question. The facts have been marshaled logically and presented clearly and unemotionally.

The essential conclusions are that at present, there is no justification for regarding *Treponema pertenue* of yaws and *T. carateum* of pinta as valid species that syphilis, yaws, pinta, bejel and other so-called "syphilitic" are all caused by *T. pallidum* and that the maladies named should be regarded as different patterns or syndromes of a disease that is fundamentally the same. Hudson recognizes that the differences between yaws and syphilis are often but not always so pronounced that a layman can distinguish them readily and he favors retention of the accepted names for the various clinical entities or syndromes caused by treponemes.

The reviewer accepts the conclusions and believes that physicians who are interested in any form of treponematosis will wish to read Hudson's presentation of the subject.

The Ego and the Mechanisms of Defense. By Anna Freud. Translated from the German by Cecil Baines. 12th cloth, 196 pp. New York: International Universities Press, Incorporated, 1946. \$4.00.

It must be stated at the outset that this small book will not be understood by the uninitiate or neophyte in psychiatry, particularly by those without a goodly quantity of psychoanalytic exposure. The text starts with what has been controversial in previous considerations of the functions and constituents of the ego. Then chapter by chapter attempts are made to depict the ego in the light of its defenses against many awe-inspiring opponents. This process of construction is carried on—as in many psychoanalytic presentations—as though the ego is and superego were as tangible and discrete "psychic institutions" as they seem to the analysts. The various well-known ego defenses from "introjection" "inversions" and "superego" attrition are described but with relatively little illustrative case material.

In many sections of the text the discussions point out so many controversial issues that the reader receives an impression of being in the midst of an informal psychoanalytic society subcommittee meeting whose chairman is proposing or dispensing with classifications. An example is the following quotation (Chapter IV):

According to the English School of analysis, Introjection and projection, which in view should be assigned to the period after the ego has been differentiated from the outside world, are the very processes by which the structure of the ego is developed and for which differentiation would never have taken place. . . . the chronology of psychic processes is still one of the most obscure fields of analytic theory. It will probably be best to abandon the attempt so to classify them and, instead, to study in detail, the situations which call forth the defensive reactions.

To the reviewer, there did not appear to be any clear differentiation between anxiety and affect against which the ego must defend itself. Nor were the superego and the parental prohibitions against which the child may not transgress differentiated—childhood neurosis thus being arbitrarily separated from adult neurosis. In other sections the discussion did not distinguish between childhood and adult affect and anxiety.

Quite properly, the author stated (perhaps not emphatically enough) that the revelation of ego defenses makes the latter inoperative and may weaken the ego so as to advance a pathologic process.

The tried and tested case of Little Hans was again used to illustrate aggressive drives, resulting fears and generalized fantasies—this time as ego defenses. Interesting deductive analyses of animal and circus fantasies and childhood stories are given as phases of the infantile(?) ego. These were

related to productive symptoms in the adult psychotic patient. It was also pointed out that parents frequently encourage escapes from reality in their children by inducing fantasies and adult impersonations of pleasurable type, the criteria of acceptance for these are then proportional to the consciousness of the symbols employed.

Interesting examples of reversal of aggression anxiety were given to illustrate identifications with the aggressor as developmental in superego formation.

The phenomena at puberty were related to those occurring in infantile and involutional eras in a brief space (Chapter XI). Here the ego was again described as being rendered *hors de combat* between the immutable id and the inevitable superego, the result being the liberation of genital territory or its control by both ego and superego.

A brief discrete attempt was finally made to differentiate normal from pathologic features of ego defenses during puberty. The answer was qualified with provisos. The concluding chapter extols the ego by the magnitude of its defenses.

By an unusual amount of scrutiny the reviewer found many novel and useful items in this book. This may be possible for others quite well versed in analytic terminology. For those not so prepared the efforts necessary to learn from this text may outweigh its usefulness.

Gastroenterology in General Practice. By Louis Pelner, M.D. With the collaboration of Louis A. Held, M.D., and contributions from Alexander Lewitan, M.D., Samuel Waldman, M.D., and Siegfried W. Westing. 8°, cloth, 285 pp., with 108 illustrations and 15 tables. Springfield, Illinois: Charles C. Thomas, 1946. \$7.50.

This book is designed for the busy practitioner and medical student. It will not appeal to the expert in gastroenterology. It is planned as an everyday handbook rather than a complete reference work and contains much useful information, well classified and clearly presented, with rarely an opinion that can be questioned. It attempts to cover the whole subject of gastroenterology in about two hundred and sixty pages, including pathology, symptoms, physical examination, laboratory tests in detail and treatment, with the result that it presents rather brief pictures of some important subjects, such as the surgical treatment of bleeding ulcer and pyloric obstruction and the medical treatment of gastritis. Only two diseases of the liver are described in detail—portal cirrhosis and cholecystitis. Less frequent conditions, such as tumors of the liver and polyps and diverticula of the stomach and duodenum, are omitted, the importance of prepyloric ulcer in the stomach is not mentioned.

Tables of differential diagnosis and diets are freely used, and the book is fully illustrated with roentgenograms that, for the most part, are excellent. About two thirds of the book consists of text, and about a third of illustrations, tables and diet lists. It is possible that the use of tables is somewhat overdone.

The arrangement of chapters is unusual. The work begins with history taking, and one proceeds two thirds through the book before simple laboratory methods are reached. It would seem simpler to put all the diseases of the bowel together, and diseases of the liver and gall bladder in sequence. The author does well to limit the liver-function tests to thirteen or fourteen instead of the twenty to fifty that are sometimes mentioned. It is unfortunate that he has not included two of the simplest and best and most modern tests—the thymol turbidity test of the blood serum and the Harrison spot test for bilirubin in the urine.

Functional diseases of the gastrointestinal tract are mentioned throughout the volume. At the end of the book there are three chapters—one on psychosomatic symptoms, one on disease and the other on simple methods by which the general practitioner can use the book. The preface and index are excellent.

of the Bronchial Tree With special reference to lung abscess. By R. C. Brock, M.S. (Lond.), M.D. 8°, cloth, 96 pp., with 142 illustrations. Ford University Press, 1946. \$12.00.

of this book successfully justifies his criticism that the physician has not yet learned to approach

the diseases of the lungs from the point of view of the segmental distribution of the bronchi. Only such knowledge will, he contends, enable a surgeon adequately to deal with conditions such as septic pneumonia and lung abscess. This is a stimulatingly instructive book. The exceptionally clear photographs—in color and in black and white—of metallic casts of the bronchial tree, made with the lungs in situ, the accurate drawings, and the clear bronchograms, both normal and abnormal, give considerable support to this point of view. This book deals with bronchial embolism and posture in relation to lung abscess, the level of the interlobar fissures of the lungs, the right upper lobe, the left upper lobe, the middle lobe, the lower lobes and the whole lung (anomalies and compound abscesses). The reviewer finds this book useful and provocative. The author's scholarly approach in presenting the material should place all physicians and surgeons in his debt. There can be no question that this book should be on the shelves of every medical-school and hospital library and in the personal libraries of those concerned with diseases of the chest.

An Integrated Practice of Medicine. By Harold T. Hyman, M.D. Four volumes and index volume. 8°, cloth, 4141 pp., with 1184 illustrations (305 in color) and 319 diagnostic tables. Philadelphia: W. B. Saunders Company, 1946. \$50.00.

This is an unusual system of medicine. Compiled largely by one writer, it comprises four large volumes and contains many millions of words. The task of putting it together must have been prodigious.

The author wished to supply the general practitioner with a modern handbook that would deal with all phases of modern medical work. No barriers of specialty practice have been permitted to obstruct the landscape. A pregnant mother or a patient with appendicitis, tuberculosis or any other ailment needs competent medical advice, and how to give this is described.

Clearly, it is impossible for any reviewer to do more than nibble at the various chapters in a work of such magnitude. This particular reviewer has enjoyed his acquaintance with the book as obtained in this manner. He believes that the thousands of physicians for whom it was written will like it, will learn much from it and will be grateful to the author.

Your Rheumatism and Backaches. By Joseph D. Wassersug, M.D. 8°, cloth, 254 pp. New York: Wilfred Funk, Incorporated, 1947. \$2.50.

This book is written to give the layman insight into the causes and treatments of symptoms and signs that are commonly labeled rheumatism or backache. It is a worthwhile endeavor for the occasional intelligent patient who requests further information to understand and follow treatment more effectively.

It is far more difficult to write a helpful and readable book for the laity than to write one for physicians. Most books of this type are written by men of wide clinical experience and deep understanding of the patient's problem. Because the author is a young man, a number of minor faults must be overlooked in this book. In later editions, less quoting from the writings of other men and a more critical analysis of the effectiveness of the treatments described, with illustrations drawn from the author's own experience, may be expected. An important omission—the most important in pre-health education—is the absence of any discussion of preventive measures that the patient may apply. Many insurance companies as well as a number of physicians, have attempted discussions of the public-health aspects of these conditions.

The material comprising this book is well arranged. It is written in an interesting, readable style. It should be a helpful book for the lay reader.

Parenteral Alimentations in Surgery With special reference to proteins and amino acids. By Robert Elman, M.D. 8°, cloth, 284 pp., with 31 figures and 21 tables. New York: Paul B. Hoeber, Incorporated, 1946. \$4.50.

The frontiers of surgery were long restrained by a lack of appreciation of the significance of water, electrolyte and protein requirements in patients subjected to operation. During the past half century a body of knowledge regarding

basic needs and their fulfillment has accumulated. The clinical application of this information has contributed materially to the dramatic expanse of surgical endeavor and to the significant reduction in mortality and morbidity of major surgical procedures.

This text is a comprehensive discussion of the evolution of the place of therapeutics by an authority whose original contributions to the development of parenteral protein formulation have been outstanding. It deals adequately with the biochemical basis of nutritional requirements as well as with the technical methods of their accomplishment by parenteral means.

Cardiovascular Diseases By David Scherf, M.D. and Linn Boyd, M.D. Second edition. 4°, cloth 478 pp. with 6 illustrations. Philadelphia: J. B. Lippincott Company, 1946. \$10.00.

This deservedly popular text has been improved by the inclusion of important new material. In particular a reasonably adequate treatment of the subject of rheumatic fever eliminates a serious omission in previous editions. The authors continue to pivot their discussion of diseases of the heart around specific structural abnormalities rather than etiologic factors. For instance, tricuspid stenosis, tricuspid regurgitation, mitral stenosis and mitral regurgitation are taken up as individual entities without emphasis on their common rheumatic origin. Although space is given to consideration of rare types of myocarditis, one looks in vain for mention of the important role that the myocardial lesion plays in the cardiac failure of chronic rheumatic valvular disease.

The book gives the impression of having been compiled from a series of lectures—each complete and excellent in itself but the whole lacking somewhat in integration. A good bibliography is appended to each chapter.

Allergy in Theory and Practice By Robert A. Cooke, M.D. In association with Horace S. Baidwin and others. 1°, cloth, 572 pp., with 1 color plate. Philadelphia: W. B. Saunders Company, 1946. \$8.00.

Each year the American College of Physicians sponsors a variety of postgraduate courses and one of the most popular is always been that on allergy directed by Dr. Robert A. Cooke, of New York City. This volume is a written account of the teaching to which his pupils have been thus exposed.

The book is excellent—a collaborative enterprise that ties together a vast amount of allergic information. Dr. Cooke, its leader, has written several chapters, including one on medical education and allergy that gives his ideas on so broad a problem with both clarity and brevity. The ordinary aspects of allergy are discussed by others of the team who are experts not only as clinicians but also as investigators and teachers.

Although most of the subjects that come under discussion are clinical in nature, the basic sciences on which allergy is founded are not forgotten. Hence the topics of chemistry, pathology and immunology receive due consideration. At the end of almost every chapter is a concise bibliography so that any student who wishes to dig more deeply into any phase of allergy receives good directions.

On the whole, this textbook is certain to be successful. All students, whether they are undergraduates or postgraduates, practitioners or specialists, will wish to study it. It is recommended wholeheartedly.

Uterine Contractility in Pregnancy. A study of the contractions of pregnancy and labor under normal and experimental conditions By Douglas P. Murphy, M.D. 4°, cloth 134 pp., with 64 illustrations. Philadelphia: J. B. Lippincott Company, 1946. \$5.00.

The Larnard tocograph is an instrument that, when strapped to the abdomen of a pregnant woman, records by means of a pen writing on a moving strip of paper the frequency and amplitude of uterine contractions, as well as the degree of uterine tone. With this device Murphy has made three thousand one hundred and fifty-four observations on 1153 subjects and has arrived at the following conclusions: the character of uterine contractions varies in different persons;

the characteristic contractions of a given patient follow a distinctive pattern throughout pregnancy and labor; the first significant rise in uterine activity may be detected in the average woman at about the twenty-first week of pregnancy, and there is a period of relative quiescence up to the thirty-fourth week, one of nonrhythmic activity from the thirty-fifth to the thirty-eighth week and a final period of rhythmic activity in the last two weeks.

Murphy believes that if a subject exhibits uterine motility in early pregnancy or a high degree of rhythmicity during pregnancy she will manifest a satisfactory quality of uterine motility during labor. Inertia according to the author more frequently follows a poor pattern of contraction than an unsatisfactory quality of activity.

In the treatment of inertia Murphy states that pituitary extract may be used safely in the absence of fetopelvic disproportion if there is no excessive elevation of uterine tone as revealed by the tocograph.

Murphy's work with the tocograph is a distinct contribution toward the study of the physiology of pregnancy and labor. Its value, however, would have been enhanced if he had made more consecutive observations during both pregnancy and labor on a large number of patients. Moreover from the practical point of view much of the information furnished by the instrument can be obtained by the trained hand of the experienced obstetrician.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Nutritional and Vitamin Therapy in General Practice By Edgar S. Gordon, M.D., Ph.D., associate professor of medicine, University of Wisconsin Medical School. Third edition. 8°, cloth 410 pp. with 47 figures and 23 tables. Chicago: Year Book Publishers, Incorporated, 1947. \$5.00.

The author published the first edition of this book in 1940 jointly with E. R. Sevinghaus and this third edition has been revised to include the new information in the literature since 1942. The volume includes material on dental problems in nutrition and on the economic side of clinical nutrition, as well as valuable tables on market lists for meals of low and moderate cost and on the nutritive values of selected foods. An appendix lists commercial vitamin preparations. A good index completes the volume which is well printed with a good type on light soft paper that is pleasing to the eye. It is worthy of note that the standard of medical book publication is steadily increasing in the post war era.

Milk and Food Sanitation Practice By H. S. Adams, B.S., chief Bureau of Environmental Hygiene, Division of Public Health, Minneapolis, and lecturer, School of Public Health, University of Minnesota. 8°, cloth 301 pp. with 65 illustrations. New York: The Commonwealth Food, 1947. \$3.25.

This textbook is written for students of public health and workers in health departments who have charge of the sanitary control of milk and food supplies. The place of education in the sanitation program is stressed. The text is divided into two main divisions: milk sanitation and food sanitation. Each division has a bibliography of selected references. A chapter is devoted to a short history of milk control, with a full discussion of the severe epidemic of septic sore throat traceable to the use of raw milk in Lee, Massachusetts, in 1928. The following chapters consider the milk control program: the essentials of sanitary milk production, the various aspects of pasteurization, laboratory procedures used to evaluate milk supply and the sanitary control of frozen desserts. The food division is in three parts: the food control problem, with a discussion of federal, state and local inspection; essentials of food-establishment sanitation; and the instruction and training of food handlers. Eleven appendices are devoted to important supplementary information, among which may be mentioned essential and special food field equipment, food poisoning and infectious diseases for the instruction of food handlers, the use of DDT as an in-

secticide and a list of films relating to milk and food sanitation. The material is well organized, the text well written, and the volume well published in every way. The book is recommended for all medical, public-health and public libraries and should prove valuable to all persons interested in the subject.

Penicillin Therapy, including Streptomycin, Tyrothricin and Other Antibiotic Therapy By John A. Kolmer, M.D., Dr. P.H., Sc.D., LL.D., L.H.D. Second edition. 8°, cloth, 339 pp., with 27 illustrations and 37 tables. New York: D. Appleton-Century Company, 1947. \$6.00.

This new edition has been largely revised and in part rewritten, and it has been enlarged by the addition of new material. New chapters have been added on the antibiotic agents other than penicillin and on antibiotic therapy in relation to veterinary medicine. In the first edition the clinical use of antibiotic agents in the treatment of various diseases was discussed from the standpoint of etiology, but in this edition the subject is discussed under pathologic entities. It is hoped that this arrangement will prove more valuable to clinicians. A long list of selected references is appended to each chapter. The volume is well printed with a good type on good paper and is recommended as a reference source for medical libraries and physicians.

Parergon. Third edition. Fo. paper, 208 pp. Evansville, Indiana: Mead Johnson and Company, 1947. \$5.00.

This edition reproduces the art of American physicians in various mediums. Two hundred and five pages are devoted to reproductions of the work. The quality is high, and some of the work is of a professional standard. There is a feature article on physicians as artists. The front cover is devoted to panels depicting Apollo, Aesculapius and Hygieia, and the back cover illustrates the restoration of the temple of Aesculapius at Epidauros. A number of Boston and Massachusetts physicians are represented in the selections. An index of artists is included in the volume. This book should be owned by every physician interested in the fine arts and should be in the historical collections of all medical libraries.

The Pharmacopoeia of the United States of America. By authority of the United States Pharmacopoeial Convention, Washington, 1940. Thirteenth revision (USP XIII). 8°, cloth, 957 pp. Easton, Pa.: Mack Publishing Company, 1947. \$8.00.

This revision is official from April 1, 1947. In the compilation of this edition the contents have been restricted to substances that reflect the best state of the medical knowledge of today and to preparations that may be most efficiently administered or used. For the first time English titles are given first, followed by the Latin equivalents. The revision of the *Pharmacopoeia* is continuous, and from time to time supplements listing new admissions are published. The excellence of publication has been maintained despite current difficulties. This standard reference work should be in all medical libraries.

Studies from the Rockefeller Institute for Medical Research. Reprints. Vol. 130. 8°, paper, 666 pp. New York: The Institute, 1947. \$2.00.

This volume is made up of reprints of articles originally published in various periodicals during the last part of 1946 and brought together in one volume for convenient reference. The articles have been repaged consecutively, and an author and a subject index supplied.

Physician's Handbook. By John Warkentin, Ph.D., M.D., and Jack D. Lange, M.S., M.D. Fourth edition. 12°, paper, 282 pp. Chicago: University Medical Publishers, 1946. \$1.50.

This pocket manual, first published in 1941, has been revised to include new material that has appeared since the publication of the last edition in 1944. The scope of the book has been extended to serve as a ready reference source for many types of medical and dental practice, and to include a relatively complete laboratory manual. Its popularity and usefulness are attested by the need of four editions in six years.

Tuberculosis As it comes and goes. By Edward W. Haye, M.D., associate professor of tuberculosis, College of Medicine, Evangelists, Los Angeles, member of the attending staff, Los Angeles County Hospital, Division of Tuberculosis, director of tuberculosis, Imperial County, California, and medical director and physician-in-charge, Maryknoll Sisters Sanatorium, Keane Sanatorium and Lair Sanatorium, Morrovia, California. With chapters by Laurence de Rycke, Ph.D. Second edition. 8°, cloth, 220 pp., with 92 illustrations. Springfield, Illinois: Charles C. Thomas, 1947. \$3.75.

This popular manual designed for the sufferer from pulmonary tuberculosis is written in plain, nontechnical language and discusses the cause and nature of the disease and its treatment. The material is well organized and the chapters on classification and mechanical therapy are well illustrated with sketches from x-ray films. The short chapter on history could have been omitted without detracting from the value of the manual. The short quotation "Tuberculosis as old as mankind" would be sufficient for a book of this type and would carry more weight than the sketchy history. De Rycke has written two important chapters on suggestions to patients and to visitors. The text is printed with a beautiful, clear, large type on good paper, a delight to weary eye. The book should prove useful to patients as well as to physicians interested in pulmonary tuberculosis. It is recommended for public and medical libraries.

Aging Successfully. By George Lawton, M.D. 8°, cloth, 266 pp. New York: Columbia University Press, 1946. \$2.75.

This is a book for the layman and is not intended for the student or practitioner of geriatrics. It is written in a easy narrative style and covers the problems of advancing age in its many aspects. Dr. Lawton believes that the best time to prepare for old age is in childhood but that it is never too late to begin, although the task becomes increasingly difficult with the advancing years. To grow old successfully requires individual thought and effort. There is nothing that can completely erase illness, infirmity, poverty, loneliness, frustration and disaster. Of particular interest are the chapters on jobs after fifty, retirement, love at maturity, relations with younger persons and the philosophy of the aged. The author stresses the need of returning to an occupation or vocation. He discusses frankly and soundly the relations of old and young persons. Interspersed throughout the text are many stories pertinent to the problems under discussion. The reviewer, being technically near old age, favorably impressed by the soundness of the advice and suggestions given by Dr. Lawton and by his analysis of the problems confronting the aging person in various situations. This book should be in all libraries, both general and medical, and can be read with profit by young and old of both sexes.

NOTICES

VAN METER PRIZE AWARD

The American Association for the Study of Goiter and Thyroid Disease offers the Van Meter Prize Award of three hundred dollars and two honorable mentions for the best essays submitted concerning original work on problems related to the thyroid gland. Provided essays of sufficient merit are presented in competition, the award will be made at the annual meeting of the association, which will be held in Toronto, Canada, May 6, 7 and 8, 1948.

The competing essays may cover either clinical or research investigations, should not exceed three thousand words in length and must be presented in English, a typewritten double-spaced copy should be sent to the corresponding secretary, Dr. T. C. Davison, 207 Doctors' Building, Atlanta 3, Georgia, not later than February 1, 1948.

A place will be reserved on the program of the annual meeting for presentation of the winning essay by the author if it is possible for him to attend. The essay will be published in the annual *Proceedings* of the association. This will not prevent its further publication, however, in any journal selected by the author.

STREPTOMYCIN THERAPY FOR CERTAIN INFECTIONS OF INTESTINAL ORIGIN*

MAJOR EDWIN J. PULASKI, M.C., A.U.S., AND COLONEL WILLIAM H. AMSPACHER, M.C., A.U.S.

SEVERAL reports have already been published concerning the laboratory and clinical investigations on the efficacy of streptomycin in various infections carried out in Army hospitals under the auspices of the Surgeon General during the past eighteen months.¹⁻⁴ The purpose of the present communication is to enlarge on and bring up to date experience with treated infections of intestinal origin. The Army series is compared with the cumulative experience in these infections as recently reported by the Committee on Therapeutics and Other Agents of the National Research Council.⁵

BRUCELLOSIS

The most recent report of the Committee revealed that, as of September, 1946, a total of 45 patients with brucellosis had been treated with streptomycin, of whom 15 showed no alteration in the course of the illness.⁶ The other 30 patients showed a decrease in fever while under treatment. Two relapses occurred in the 29 patients in this group who were followed up from three to eight weeks. Five of the 30 apparently improved patients received less than 3 gm. of streptomycin daily, and 25 received 3 or 4 gm. daily for periods varying from five to sixteen days. Of the 15 unimproved patients, 5 received from 3 to 4 gm. daily, and the others received 2 gm. daily.

All cases investigated by the National Research Council were acute and culturally proved. Insufficient time has elapsed to permit a determination of the effect of streptomycin on the relapse rate in brucellosis, but its effect in the acute disease is evidently not pronounced. It was the opinion of the Committee that if streptomycin is used in brucellosis, the minimum dose should be at least 4 gm. daily for fourteen to twenty-one days.

Up to the present time 25 cases of brucellosis have been studied in the Army streptomycin program, of which 12 were acute and 13 chronic. The disease was classified as chronic when fever and symptoms had continued for a year or more. Blood cultures were positive for *Brucella* in 11 of the 12

acute cases, and the organisms were found to be sensitive to 0.5 to 1.0 microgm. per cubic centimeter of streptomycin. A bacteremia was present in 2 of the chronic cases. Most of the patients had positive skin reactions to killed *Brucella* organisms, and *Brucella* agglutinins in titers higher than 1:80 were obtained in the blood in all cases. Titers ranged from 1:320 to 1:5120 in the acute cases and from 1:80 to 1:1280 in the chronic cases.

Because these patients were observed over a period of fourteen months there was considerable variation in the amount of streptomycin that they received, as well as in the duration of treatment. By present standards some received too small doses for too short a time for beneficial results to be anticipated. The largest daily dose was 6 gm.,—in 2 cases, for a fourteen-day period,—but some patients received only 1 or 2 gm. daily for ten days. The intermittent intramuscular route was used in all cases.

The over-all results, regardless of whether large or small doses were used, indicated clearly that streptomycin is not effective in brucellosis. In the acute type of disease bacteremia disappeared in some, although not in all, cases while the drug was being administered, but recurrences were frequent, occurring in 5 cases. The relief of symptoms and improvement in appetite that some patients experienced under treatment could quite as well have been due to expected natural remissions and to psychologic factors as to streptomycin.

The following cases demonstrate typical responses to streptomycin therapy in brucellosis.

CASE 1. A 28-year-old Army officer had been in good health until December 12, 1945, when, during a leave, he developed chills, fever, night sweats, headaches, asthenia and anorexia. After ineffective treatment with sulfadiazine he was admitted to an Army regional hospital on January 4, 1946. When questioned he stated that he was not aware of having ingested raw milk or dairy products made from raw milk.

Physical examination showed a wan and listless man. The only other positive findings were a reddened pharynx and a palpable but not tender spleen.

Examination of the blood revealed a white-cell count of 6000, with 61 per cent lymphocytes. A blood culture grew colonies of *Brucella*.

Between January 4 and 15 asthenia and anorexia persisted and there were daily afternoon temperature elevations to 101° and 102°F. Sulfadiazine was begun on January 15.

*From the Surgical Research Unit, Brooke General Hospital, Army Medical Center, Fort Sam Houston, Texas.

This project was carried out as a part of the study being made under the direction of the Army Medical Research and Development Board, Office of the Surgeon General.

and discontinued on January 27, after 68 gm had been administered. The temperature, which had fallen to normal, began to rise again on February 12, when a second course of sulfadiazine was begun, in combination with subcutaneous injections every 3rd day of a suspension of heat-killed *Brucella*. Blood cultures remained positive, and the patient showed no improvement. The combined therapy was discontinued on March 11, and 1 week later the patient was transferred to Halloran General Hospital.

Streptomycin therapy was begun on March 21 by the intramuscular route in doses of 0.5 gm every 4 hours. At the end of 21 days penicillin in doses of 40,000 units was added to each injection for an additional 5 days. Transfusions of citrated blood were also given. A mean blood serum level of 16 microgm per cubic centimeter was maintained, which, since the organism was sensitive in vitro to 0.5 microgm per cubic centimeter, meant that the blood level was many times the concentration required for bacteriostasis in vitro.

Throughout the period of treatment, there had been inconstant albumin and casts in the urine, and 24 days after treatment had been begun, the patient complained of dizziness and had difficulty in focusing his gaze. The streptomycin was discontinued 48 hours later. For the next 8 days the temperature rose only to 100°F daily, but on April 24 the elevations assumed the former level of 102 and 103°F. On April 29 the blood culture was again positive. The organisms recovered were inhibited by 0.5 microgm of streptomycin per cubic centimeter, just as they had been originally.

On May 21 streptomycin was resumed in the same intramuscular doses as had previously been given, and on the assumption that the drug had not previously reached all foci of infection, it was also given by mouth in daily doses of 2 gm. At the end of 1 week no obvious improvement had occurred under this regime. Streptomycin was then discontinued by mouth but was continued by the intramuscular route, and the patient was given, in addition, 6 gm of sulfadiazine daily. The temperature fell rapidly during the next 14 days, and as of December 1, there had been no recurrence. The patient felt well, had an excellent appetite and was gaining weight. No remission of similar length had occurred since the onset of illness, and it is believed that observation has been carried out for a sufficient length of time to regard the patient as apparently cured.

CASE 2. A 30-year-old bacteriologist was hospitalized on July 27, 1945, complaining of "high fever" and "weakness" for the preceding 48 hours. These symptoms had followed a mild episode of diarrhea. Temperature elevations persisted after hospitalization, and blood cultures on three different occasions were positive for *Brucella*, which was determined to be sensitive in vitro to 1 unit of streptomycin per cubic centimeter. Streptomycin therapy was begun on August 11, the patient receiving 0.2 gm intramuscularly every 4 hours for 10 days. The fever subsided by lysis, and the temperature reached normal on the 8th day of treatment. Three days later a thrombophlebitis developed in the deep veins of the left leg but gradually subsided. An episode of pneumonia, which began on September 8, responded promptly to penicillin.

During September two febrile episodes were associated with malaise and generalized lymphadenopathy, and a third episode of the same kind occurred in October. At that time a blood culture was again positive for *Brucella*. Streptomycin therapy was resumed, the patient receiving 0.33 gm by the intramuscular route every 4 hours for 10 days. The febrile course was completely unchanged, and there were daily temperature elevations to 102°F, but blood cultures became negative. The streptomycin level in the blood reached 16 units per cubic centimeter. Twenty-four hours after treatment had been discontinued the temperature returned to normal, but after a short interval it again became elevated. Since streptomycin was obviously of no value, it was not resumed. The patient has continued to run a course typical of undulant fever.

The course in Case 2 is characteristic of the uniform lack of response to streptomycin therapy in all acute and subacute cases of brucellosis. Case 1 is likewise typical of the response in acute cases: the blood cultures tended to remain positive regardless of the dose of streptomycin given and

the route of administration. These results are what might be expected. *Brucella* infections are characterized by the distribution of organisms through the lymphatic system and the blood stream, with localization in the gall bladder, spleen and lymph nodes, as well as in other structures. Previous studies on the disposition of streptomycin given parenterally, in cases in which death occurred in the course of treatment, indicate that the drug does not reach the lymph nodes in assayable amounts, whereas only small amounts can be recovered from the parenchyma of the spleen.² Levels in bile from the gall bladder and from the common duct are about a quarter as high as that in the blood serum. These observations are in accord with those of Reimann, Price and Elias⁷ and Nichols.⁸

A remarkable feature of Case 1 is the fact that the susceptibility of the organisms to streptomycin, as shown by the blood culture, was in no way altered after twenty-six days of intensive therapy. Two possible explanations were postulated that the drug did not reach all foci of infection, and that the organisms were unique in not developing the expected drug-fastness usual under these circumstances. On the assumption that the first explanation was correct, streptomycin was given by mouth, in addition to its administration by the intramuscular route, but without effect on the course of the disease. On the assumption that the organisms were unique the culture was sent to the Merck Institute at Rahway, New Jersey, to determine whether fastness to streptomycin in vitro could be developed. The studies led to the conclusion that the organism isolated in this case followed the usual pattern and had become habituated to increasing concentrations of the drug. The findings therefore support the hypothesis that streptomycin does not reach the foci of infection in brucellosis in lethal concentrations.

In Case 1 the prompt response to the combined administration of streptomycin and sulfadiazine, after treatment by streptomycin alone had had no effect on the acute disease, led to the similar combined treatment of another patient, who had also shown no response to streptomycin alone. A similarly prompt and favorable response was obtained, and the patient has remained well over a six-month period of observation. It is still too early to state that permanent arrest of the disease was obtained in either case, but the combined method of treatment seems to deserve further trial as part of the general therapy of brucellosis. If it is employed, it is recommended that the dose of streptomycin be 0.5 gm intramuscularly and the dose of sulfadiazine 1 gm orally every four hours, and that treatment be continued for fourteen days or more.*

*Since the completion of this paper, 4 additional patients with the acute or bacteremic form of undulant fever have received combined streptomycin and sulfadiazine therapy for an average period of seventeen days. Three had a prompt remission, which has been sustained. In the fourth, a twenty-four-year-old woman, from whom *Brucella* could not be cultured, this therapy had no effect on the course of the disease.

TYPHOID AND PARATYPHOID FEVERS

Schatz and his associates¹ were the first to report that streptomycin has a potent bacteriostatic action *in vitro* on the typhoid-dysentery-Salmonella group of pathogens, an observation that our studies subsequently confirmed.² A wide variation in range of sensitivity occurred when large numbers of the same species were examined. It is of considerable importance, however, that over 80 per cent of the organisms were found to be inhibited by 16 microgm per cubic centimeter, which indicates that the administration of 0.4 gm of streptomycin intra-

of streptomycin varying between 1 and 5 gm were given daily for five to nineteen days, the majority of patients received 4 gm daily for seven or eight days. Results were reported according to the time at which treatment was begun. In 18 of 28 cases in which treatment was begun before the eighteenth day of illness the temperature was normal before the twenty-eighth day, but in the other cases elevations persisted for periods ranging from twenty-nine to fifty-six days. In 25 cases in which treatment was begun after the eighteenth day temperature elevations persisted for twenty-eight days or more. In 1 case in which treatment was begun on the

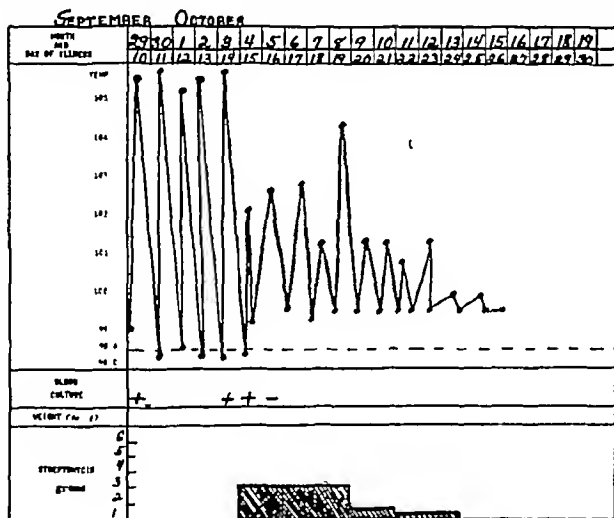

FIGURE 1

This patient, a twenty-eight-year-old woman, presented the classic signs and symptoms of typhoid fever, confirmed by positive blood and stool cultures. She derived no benefit from parenteral streptomycin therapy. The effectiveness of the drug administered orally is debatable, since the organisms were reported resistant *in vitro*.

muscularly every four hours is sufficient to inhibit in blood serum the majority of the bacteria tested, since this dosage maintains the necessary blood level of the drug.

The fact that streptomycin is poorly absorbed from the gastrointestinal tract and is not inactivated by the contents of the bowel suggests that its oral use in certain susceptible infections is logical and useful. The oral administration of 4 gm daily by mouth causes 0.01 to 0.02 gm per gram of feces to appear in the stools and rapidly eliminates gram-negative bacteria from the bowel.⁷

The clinical experiences reported in the literature in typhoid and paratyphoid fevers are unfortunately somewhat at variance with results obtained in the laboratory.⁶⁻⁸ In the 51 cases of typhoid fever studied by the National Research Council⁶ doses

every eighth day of illness the temperature was normal by the twelfth day, the blood culture became negative during treatment, but the stools were still positive a month after therapy had been discontinued. In 15 cases the oral as well as the intramuscular route was used, without apparent difference in results.

The Committee reported that the number of patients treated was insufficient to determine whether the fatality rate in typhoid fever could be reduced by the use of streptomycin and believed that to date no evidence was at hand to indicate that streptomycin in doses of 4 gm daily could shorten the course of the disease. An interesting proof of this conclusion was supplied by the coincidence that the sister of a patient in the streptomycin-treated group developed typhoid fever simultane-

ously and that her course, without treatment, was identical with that of her sister, who had had treatment with streptomycin beginning on the fourteenth day and whose temperature had reached normal on the twenty-fourth day. The Committee pointed out the necessity of determining whether an earlier beginning of treatment (within the first seven days of illness) could shorten the duration of typhoid fever.

To date, results in 6 patients with acute typhoid fever, 3 typhoid carriers and 2 patients with paratyphoid infections in the Army streptomycin pro-

One patient died on the fourteenth day of therapy, presumably as the result of peritonitis from perforation of a Peyer's patch, which had occurred eleven days before the initiation of streptomycin therapy and which was followed by pneumonia. No autopsy was obtained.

Two of the typhoid carriers, both of whom were asymptomatic, received combined oral and systemic streptomycin therapy in doses of 4 and 2 gm respectively for a period of ten days. In both cases typhoid bacilli were still present in the feces after treatment. The remaining carrier had developed

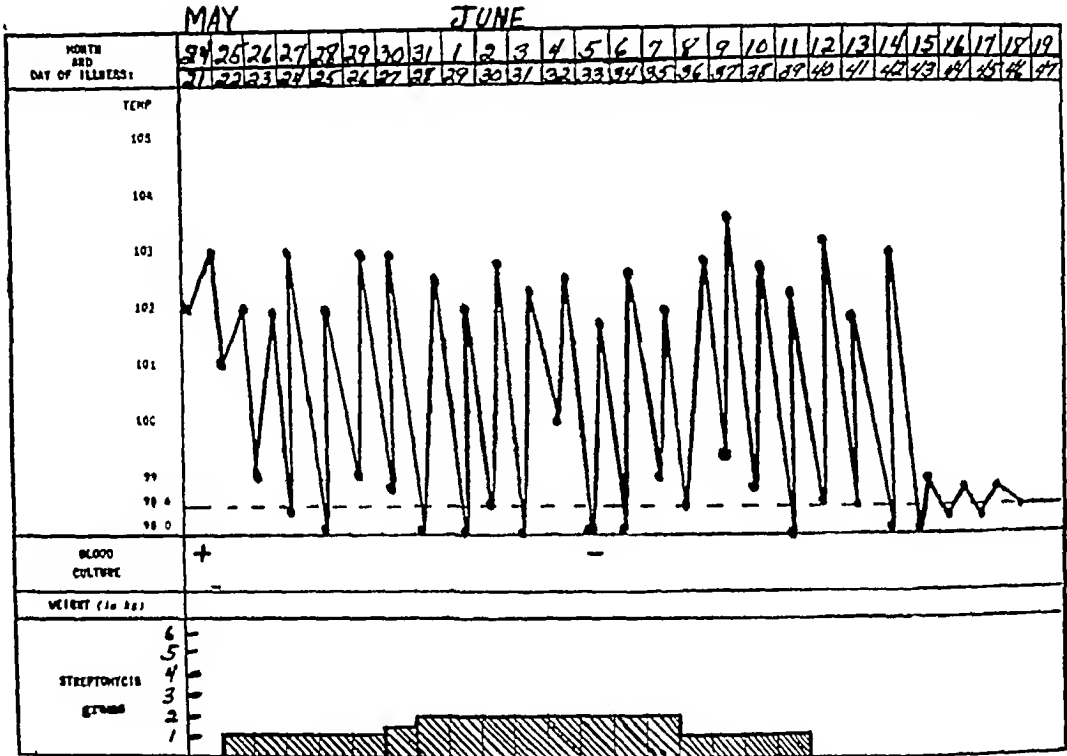

FIGURE 2

This patient, a twenty-year-old woman, who had been immunized against typhoid fever three years before, developed severe typhoid septicemia with a toxic psychosis. Streptomycin therapy had no observable effect on the course of the illness.

gram have been reviewed. The diagnosis in the acute cases was established by the culture of typhoid bacilli from the blood and the stools in every case and from the urine in 1.

Three of four strains of typhoid bacilli recovered in the acute infections were inhibited in vitro by 8 microgm of streptomycin per cubic centimeter, but the fourth strain proved drug-fast. All patients received from 2 to 4 gm of streptomycin daily for periods varying from eight to seventeen days. The combined oral and parenteral route was used in 3 cases, and the parenteral route alone in the other 3 cases. The accompanying charts (Fig 1-3) illustrate the diversity of the temperature response in relation to the dosage and schemes of dosage, as well as the effects of therapy on recovery of the etiologic agent from the blood and feces.

periostitis and osteitis of the right tibia four months after apparent recovery from typhoid fever. Typhoid bacilli were aspirated from the lesion and were also recovered from material obtained by biliary drainage. The diagnosis of typhoid osteitis was thus confirmed, and the carrier state established. Streptomycin was given for ten days in doses of 2.4 gm daily, after which the periostitis subsided and the symptoms disappeared. Four months later there was no clinical or roentgenologic evidence of infection of the bone, the Widal test became negative, and repeated cultures of urine, feces and bile showed no growth. In this case the disappearance of typhoid bacilli from the bile and from the lesion in the tibia was coincident with the administration of streptomycin.

In the following case streptomycin was apparently of value after sulfaguanidine had had no effect.

CASE 3 A 25-year-old soldier was hospitalized after an illness of 5 days characterized by headache, nausea, diarrhea, abdominal pain and fever. *Salmonella paratyphi* was isolated from the stools but not from the blood. The administration of sulfaguanidine did not affect the course, and on the 10th day of the illness streptomycin was begun in oral doses of 0.5 gm. every 4 hours. Eighteen hours after the first dose the diarrhea and tenesmus abated, and the temperature fell to normal. A total of 4 gm. (eight doses) was given. The patient continued to make an uneventful recovery and has remained well over a 1 month period of observation.

The results of streptomycin therapy in the 6 cases of acute typhoid fever were disappointing. In only 1 case did the fever end within a sufficiently short time and recovery follow in such a manner as to suggest that the drug was responsible for the favorable outcome. It is perhaps significant that in this apparently successful case the patient, a five-year-old child, received the dosage usually given to an adult (Fig 3), which means that he received approximately three times as much streptomycin as any of the other patients were given. Both the oral and the parenteral routes were used. In the other 2 cases in which sensitivity to the organism was established streptomycin therapy was apparently without effect, and it is assumed that the active foci of infection were not reached. The efficacy of streptomycin in the remaining case is equivocal, since the treatment was begun when the disease was at the stage when recovery is ordinarily expected. As noted above, streptomycin by combined oral and systemic administration is theoretically the ideal treatment for enteric fever. The usual effects from systemic administration might be expected, and oral administration, because the drug is poorly absorbed from the gastrointestinal tract and is not inactivated in it, rapidly sterilizes the bowel of susceptible gram-negative bacilli. Published results of such combined treatment, however, are inconclusive and disappointing, as in our small series.

In 2 patients who were typhoid carriers streptomycin failed to eliminate typhoid bacilli from the feces. In a third carrier disappearance of typhoid bacilli from the bile and from a bone lesion coincided with the administration of streptomycin and may be attributed to its use. The administration of streptomycin was followed by a promptly favorable response and complete recovery in 1 patient with a paratyphoid infection.

ACUTE GASTROENTERITIS AND ENTEROCOLITIS

It is now quite well established that beneficial effects in varying degrees are obtained in bacillary dysentery by the use of sulfadiazine and sulfasuxidine but that these drugs are apparently of no value in *Salmonella* infections. Penicillin is not effective in the treatment of bacillary dysentery. The acute dysenteries respond promptly to chemo-

therapy. Chronic infections and the carrier state of *Shigella* dysentery require larger doses of the sulfonamides for longer periods before optimum results are secured. Failures of therapy, relapses and the development of the carrier state can be variously attributed to late institution of therapy, premature termination of therapy, insufficient dosage and the presence of drug-resistant bacteria.

The development of a new chemotherapeutic agent—especially one that is less toxic than the sulfonamides, can be used in smaller doses and is even more effective in the treatment of gastro-

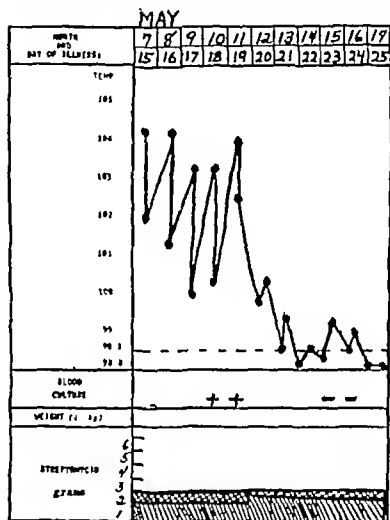

FIGURE 3

This five-year-old boy began to receive streptomycin therapy in large (adult) doses on the fifteenth day of his illness. Blood and stool cultures were negative within twenty-four hours after therapy was begun, and the temperature reached normal eight days later.

intestinal infections—naturally commands attention. Streptomycin seems to fulfill these criteria. Studies indicate that it is absorbed from the gastrointestinal tract in only small quantities, that it is excreted with the feces and that, as it is passed along to the rectum, it inhibits the growth of bacteria susceptible to it. The oral administration of 2 to 4 gm daily alters the flora of the alimentary tract, especially the gram-negative bacteria, within forty-eight hours (Fig 4). To date we have not observed or seen reported in the literature toxic manifestations following the oral administration of streptomycin. Its use in disease of the gastrointestinal tract therefore seems indicated, especially as a substitute for the sulfonamides if in any case

they prove unsuitable by reason of ineffectiveness, toxicity, sensitivity of the patient or unavailability.

The most recent communication of the National Research Council⁶ reported 2 cases of *Shigella* dysentery and 26 cases of *Salmonella* infection treated with streptomycin. Both patients with *Shigella* dysentery had previously been treated with sulfonamide drugs without result. Streptomycin, in a dosage of 15 gm daily by the intramuscular route for five days, was begun in the third month

became negative. The other 2 continued to have positive cultures and eventually died.

Seven of the 26 patients reported by the Council had enteric infections complicated by other conditions. Three had involvement of the lungs. Two of these had positive blood cultures when treatment was begun, 1 recovered, and 1 died. The third patient had negative blood cultures when treatment was begun and showed clinical improvement. Of 2 patients with *Salmonella* meningitis 1 recovered

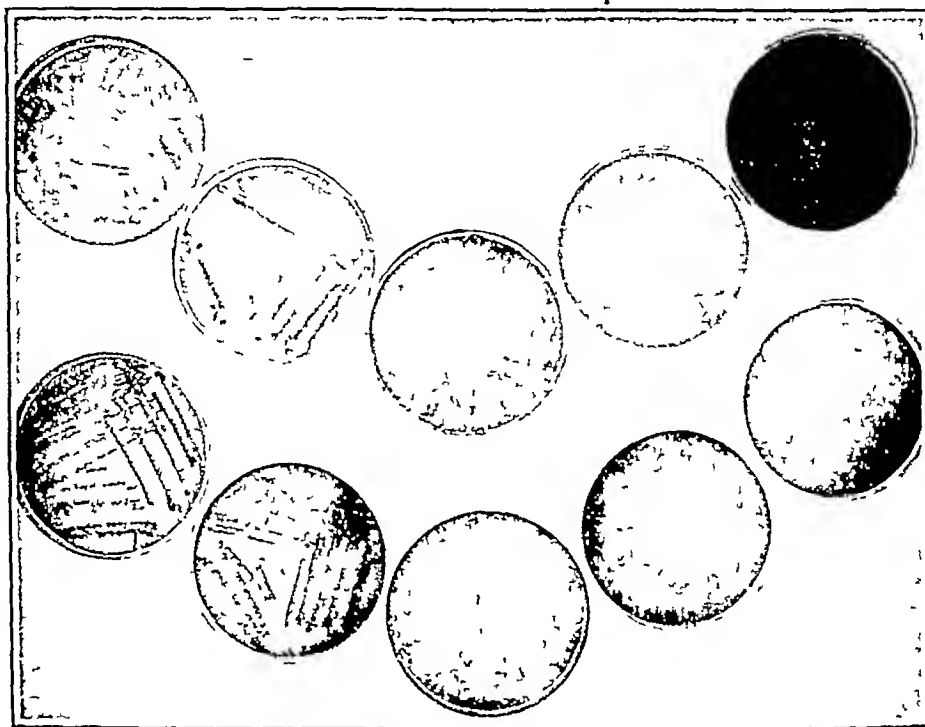

FIGURE 4 Effect of Oral Streptomycin on Fecal Flora

These plate cultures of colostomy swabs were made at twenty-four-hour intervals, they show the effect of the ingestion of 0.5 gm of streptomycin every six hours. The drug effectively suppresses the fecal flora in forty-eight hours, but sterilization is not achieved, since it does not inhibit yeasts, fungi and certain gram-positive organisms, including Clostridia, which suggests that it might be desirable after forty-eight hours to combine oral penicillin therapy with streptomycin therapy. The last plates, made forty-eight hours after the drug had been discontinued, indicate that bacteriostasis was still present.

of illness in 1 case and in the fifth month in the other. Stool cultures were positive in both cases before treatment and negative afterward. The period of follow-up observation was a month in 1 case and nine days in the other. Among the 26 patients with *Salmonella* infections 10 recovered under treatment, 2 improved under treatment and later recovered, 6 showed no improvement, and 8 died, 2 of whom had shown transient improvement in the course of treatment. Of the 19 patients with enteric involvement alone, 8 recovered, 7 were uninfluenced by treatment, and 5 died—1 of mesenteric thrombosis four weeks after treatment had been completed. Of the 5 patients in this group with bacteremia when streptomycin therapy was begun, 3 recovered and the blood cultures

under treatment, and 1, after transient improvement, died of hydrocephalus secondary to the infection. One patient was comatose when treatment was begun and died three days later, autopsy showed a complicating encephalitis. In a case in which the *Salmonella* infection was superimposed on ulcerative colitis three courses of streptomycin resulted in transient improvement, which was followed on each occasion by a recurrence of symptoms.

The average dose of streptomycin in these 26 cases was 3 gm for seven days. Treatment in 11 cases was started on the third to the sixth day of illness, and in the remainder from the seventh to the twenty-eighth day. When streptomycin therapy

was begun after the eighth day of illness only 1 patient recovered

The conclusion of the Council was that the high mortality in this series could be accounted for by the varying sensitivity to streptomycin of the various strains of *Salmonella* organisms, with the localization of the infection and complications of other diseases as possible additional factors. In view of the high mortality the recommendation was made that in *Salmonella* infections maximum doses of streptomycin be used as early as possible in the illness and that treatment be continued for at least fourteen days

Bacillary Dysentery

Our experience with streptomycin therapy in bacillary dysentery includes 10 cases. The infecting organism was *Shigella paradysenteriae* (Sonne) in 4 cases and in 6 various subtypes of *Sh. paradysenteriae* (Flexner). Five patients were treated during the first attack of illness, and the remainder after previous episodes of diarrhea. In almost every case the patient had previously been treated with either absorbable sulfonamides, such as sulfadiazine and sulfathiazole, or the unabsorbable variety, such as sulfaguanidine and sulfasuxidine, or both. Streptomycin was given in doses of 1 to 4 gm daily for periods ranging from one to twelve days. The drug was administered orally in 2 cases, parenterally in 6 and in combination in 2.

In nearly every case the results were good to excellent. The causative bacilli disappeared from the feces, and symptomatic improvement was concomitant. The response was most dramatic in cases in which treatment was begun in the first attacks, and in patients with recurrent diarrhea who received combined oral and parenteral therapy amounting to 4 to 6 gm daily for twelve days or longer. No case of relapse has been recorded in periods of observation ranging from one to four months.

The following case is presented as typical of a successful result

Case 4. A 21-year-old medical corpsman on duty in the Pacific, had been well until November 15, 1944, when he began to suffer from abdominal cramps and diarrhea. Treatment with paregon, bismuth and sulfaguanidine did not improve the symptoms. On admission to a station hospital on December 26 he was found to have hookworm ova (*Necator americanus*) in the stools but appropriate treatment produced no improvement in the original symptoms. On January 11, 1945, he was transferred to a general hospital, where he remained for 11 weeks. Treatment for hookworm was again carried out. The patient was relieved of cramps although the diarrhea persisted, and was eventually returned to limited duty. On July 21 he was readmitted to the general hospital for recurrence of cramps and was returned to the United States where he was admitted to an Army general hospital on October 5. At that time he was having four or five loose stools daily. Stool cultures showed *Shigella paradysenteriae* (Flexner V and Z). Treatment with sulfaguanidine followed by sulfadiazine produced no results, and streptomycin therapy was begun on February 19, 1946, in doses of 0.25 gm every 4 hours and was continued for 10 days. On the 7th day of treatment the temperature rose to 101 and

on the 9th day to 103°F. On the 10th day a rash on the trunk was observed. The rash disappeared and the temperature fell to normal 24 hours after treatment had been completed. In the course of treatment the stool culture became negative, and the patient had formed stools for almost the first time since the beginning of the illness. He was well at the end of a 3 month period of observation. No definite cause for the temperature elevation or the rash that developed in the course of treatment could be found and both were attributed to a possible allergic reaction to streptomycin or to a possible impurity in the product.

Salmonella Infections

Ten patients with enteric infections harboring *Salmonella* organisms in the stools received streptomycin therapy. Two had acute gastroenteritis and enterocolitis with blood cultures positive for *Salmonella* when treatment was begun. Combined oral and intramuscular streptomycin therapy for seven days resulted in elimination of the organisms from the blood stream and the feces, with relief of symptoms. No relapses were recorded. Three infants with severe diarrhea and *Salmonella* organisms in the stools were given streptomycin orally alone, in daily doses of 100 mg per kilogram of body weight for four to seven days, with attendant decrease in fluidity and number of stools and cultures negative for *Salmonella* for a follow-up period of three weeks. The remaining 5 patients had acute exacerbations of recurrent diarrhea, as well as stool cultures growing *Salmonella* organisms. Two patients were treated with streptomycin orally, without effect. Oral therapy was then combined with intramuscular streptomycin in 1 case, and three stool cultures became negative and remained so. Three patients with *Salmonella* organisms superimposed on a chronic enterocolitis received both oral and systemic streptomycin for a total dosage of 4 to 6 gm for ten to fourteen days. These patients obtained symptomatic relief during treatment, and cultures became and remained negative for *Salmonella*. Mild abdominal cramps and loose stools persisted, however, even though the *Salmonella* organisms did not reappear in follow-up cultures.

In the evaluation of these results of streptomycin therapy it must be borne in mind that acute bacillary dysentery and salmonellosis are frequently self-limiting diseases. On the other hand, the results in this small series of cases suggest that the therapeutic effect of this method is favorable. The observations reported are comparable to those made when the absorbable and nonabsorbable sulfonamides are used in susceptible cases. The results were usually favorable regardless of the method of administration employed.

Beneficial results were obtained in this series in acute infections caused by *Salmonella* and *Shigella* organisms that had proved resistant to sulfonamide therapy. Doses of 3 to 6 gm for periods ranging from three to sixteen days are probably adequate in most cases, but the larger amounts are recommended, for periods ranging from four to ten days,

to minimize the risk of development of streptomycin resistance. Since the offending bacteria are not confined to the lumen of the bowel but may penetrate into deep crevices and mesenteric lymph nodes, the combined oral and systemic method of administration seems more rational than the use of either route alone and is recommended. Evidence to date does not suggest that, as is advisable when the sulfonamides are used, streptomycin should be withheld until normal hydration is restored. Toxicity has not been observed following oral administration of the drug.

Streptomycin therapy was tested in 2 cases of amebic dysentery and proved of no value. The dosage was 5 gm daily for five and nine days, respectively, by the combined oral and systemic routes. The lack of results emphasizes the futility of employing streptomycin in any condition caused by organisms not susceptible to it.

COLITIS

The most recent report of the National Research Council⁶ includes only 1 case of ulcerative colitis on which a *Salmonella* infection was superimposed, as mentioned above. Three courses of streptomycin resulted in only transient improvement.

Our experience with streptomycin includes 16 cases of chronic idiopathic colitis and ileocolitis, in all of which the dysenteric disease had progressed from the acute to the chronic phase. In 1 case a culture revealed hemolytic streptococci. No causative organism could be isolated in any of the remaining cases. The diagnosis was based on the history, the symptomatology, positive roentgenologic observations, positive proctoscopic and sigmoidoscopic observations and the exclusion by proper tests of such specific conditions as bacillary dysentery, amebic colitis, tuberculous colitis, lymphopathia venereum and deficiency states.

Seven patients had chronic static disease. The 9 remaining patients were in the acute, active stage, with systemic manifestations. The lesions varied from a localized area in the most distal segment of the rectum to diffuse involvement of the entire large bowel. One patient had, in addition to colitis, a segmental ileitis for which an ileocolostomy had been performed. The 9 patients with extensive involvement were moderately to seriously ill.

All the patients had had a variety of previous treatments, including sulfonamide and penicillin with either no response or with only slight improvement. This is in agreement with our experience. Amelioration of symptoms has sometimes been obtained by the use of the sulfonamides and penicillin, but no significant series has been reported in which lasting remission could be directly attributed to chemotherapy. Streptomycin was given in doses ranging from as little as 1 gm up to 2 gm at intervals of three to six

hours, by the intramuscular or oral route or by both routes, for periods ranging from four to sixty-two days. Penicillin was also given in 1 case. Improvement was considered to have occurred if there was a reduction in the number of stools, a decrease in or disappearance of blood in the stools, and relief from the concomitant symptoms of toxemia. On this basis temporary improvement was observed in all acute cases except 1 in which a hemolytic streptococcus was implicated as the etiologic agent. In the cases of chronic static disease some improvement usually occurred during therapy, but it was generally undramatic and seldom permanent. The following case is not atypical.

CASE 5 A 25-year-old officer developed diarrhea in October, 1945, with bright-red blood in the stools. He was hospitalized promptly but continued to have two to fifteen bowel movements daily, many of which contained blood. Cysts of *Endamoeba histolytica* were found in the stools on a number of occasions, and significant titers (1:320) for *Shigella paradysenteriae* (Flexner Y) antibodies were demonstrated in the blood. There was positive roentgenologic and sigmoidoscopic evidence of ulcerative colitis. Courses of antiamebic drugs, sulfathiazole and penicillin, alone and in combination, failed to influence the course of the disease. Repeated transfusions of blood and plasma were necessary for correction of a marked anemia.

Streptomycin therapy was begun on May 29, 1946, in doses of 0.5 gm orally every 3 hours and was continued for 5 days. The drug was discontinued after an increase in diarrhea accompanied by temperature elevations had developed. On June 28 a second course of streptomycin was begun in the same dosage and was continued for 14 days. The dosage employed effectively eliminated the susceptible fecal flora but had no effect on the temperature elevations and diarrhea. A third course was begun on July 29, the drug being given intramuscularly in dosages of 0.4 gm every 4 hours for 7 days. There was no alteration in the course of the disease or in the bacteriologic findings, and streptomycin therapy was permanently discontinued.

In evaluating the results of streptomycin in colitis it is necessary to bear in mind two points: whether the streptomycin therapy is a part of the medical regimen in a case in which surgery is not required, or whether it is employed in the hope of controlling the active phase of the disease, so that resection can be more safely undertaken, and just what is expected from treatment. Whatever the objective of therapy, it is obvious that no chemotherapeutic agent can be expected to restore to normal the physiologic function of an intestine that has undergone irreversible changes and has become contracted and deformed by disease of long standing. All that any drug can be expected to accomplish under such circumstances is to control symptoms due to active infection.

The majority of patients treated in this small series derived some benefit during treatment with streptomycin, but over-all findings are contradictory and no particular optimism seems warranted; it could scarcely have been expected. The impression is gained from a study of these cases that future evaluation of streptomycin therapy should be on the basis of longer courses of combined oral and systemic administration.

EPIDEMIC DIARRHEA

The report of the National Research Council⁸ apparently includes no cases of epidemic diarrhea in infants. The present study comprises 13 cases of this type of diarrhea. Eight infants were received from an Army transport, which had been the scene of an outbreak of the disease, and 4 were serious cases of nonspecific gastroenteritis complicated by dehydration, toxemia and varying degrees of malnutrition that, in 2 cases, amounted to a state of marasmus. The thirteenth patient had also had gastroenteritis, and was 1 of 3 controls, she was treated with streptomycin when her condition failed to improve under the usual treatment. No *Shigella* or *Salmonella* organisms of the usual pathogenic variety could be recovered from any of these cases. *Proteus morganii* and *Pr. vulgaris* predominated in all cases, but since these organisms are present in normal stools and tend to overgrow other bacteria readily, it is difficult to incriminate them as the etiologic agents. It is believed with reasonable certainty that no single organism was responsible for the infection in any case in the group.

Because of a lack of previous experience with streptomycin in epidemic infantile diarrhea, the first 7 infants received from the Army transport were treated with small doses of the drug. Two died, forty-eight and seventy-two hours, respectively, after the beginning of therapy, as the result of severe toxemia and central-nervous-system involvement. The remaining patients were discharged in good condition and on full diets between the fifteenth and thirtieth days after admission, hospitalization was prolonged in some cases because of extensive weight loss. All these children received daily doses of streptomycin varying from 0.1 to 0.2 gm. per kilogram of body weight at four-hour intervals over periods varying from two to ten days. The eighth patient received from the Army transport was given 0.1-gm. doses at four-hour intervals for six days. Two of 3 patients with infantile diarrhea used as controls while these 8 children were under treatment with streptomycin did well under the usual treatment. The third, after a period of improvement under the usual routine, regressed and became critically ill, but recovered after the use of large doses of streptomycin.

Two babies with nonspecific gastroenteritis associated with malnutrition and dehydration, after failure of the usual treatment, were given streptomycin in daily doses of 0.3 to 0.6 gm. per kilogram of body weight and were placed on full diets at the same time. One made a prompt and dramatic recovery. The other continued to have diarrhea and fever until the daily dosage of streptomycin was raised from 0.3 to 0.6 gm. per kilogram of body weight. Although the diarrhea was controlled and the temperature began to fall, death eventually occurred from pneumonia and heart failure. Two

other infants with nonspecific gastroenteritis were treated early and vigorously with streptomycin in daily doses of 0.12 and 0.25 gm. per kilogram of body weight and showed prompt improvement. One child was discharged within twelve days, after a gain of 1 pound, 5 ounces, over a period of only eight days. When treatment was begun she was moribund, being in a state of respiratory and circulatory collapse, nervous-system involvement was manifested by convulsions, spasticity, facial paralysis, stupor and coma. When she was discharged the only residuum was a mild facial palsy.

One child, in another Army hospital, was treated by doses of 30 mg. of streptomycin orally every hour for one hundred hours. Diarrhea was controlled but recurred briefly after therapy had been discontinued. Larger doses given over a longer period might have been more promptly effective.

No conclusions regarding the value of streptomycin therapy in epidemic diarrhea can be drawn from so small a series of cases. On the other hand, it was the considered opinion of Major Irvin J. Cohen, under whom these cases were handled, that at least 4 of the 13 children are alive today because of streptomycin, which in all cases seemed to shorten the period of illness, control starvation and malnutrition and reduce the hospital stay. When a proper routine of usage has been established, a demonstrable reduction in mortality may reasonably be expected. Further studies should be conducted on infants with epidemic infantile diarrhea and nonspecific gastroenteritis by the following regimen: parenteral fluids, including blood and plasma to combat shock and restore water, electrolyte and protein balance, early oral feedings of 72 to 125 calories per kilogram of body weight if vomiting is absent, and streptomycin in adequate doses, 0.5 gm. per kilogram of body weight being regarded as the minimal daily dose. Dosages up to 1.0 gm. per kilogram of body weight should be utilized in critically ill children, regardless of age. The drug should be continued for at least a week after a satisfactory response has been obtained.

SUMMARY

The present report enlarges on and brings up to date certain streptomycin-treated cases of intestinal origin observed in the Army streptomycin program. For comparative purposes brief statements are made concerning the report of the Committee on Therapeutics and other Agents of the National Research Council on the same types of infection.

Generally speaking, the results of streptomycin therapy in acute and chronic brucellosis were poor, although in 2 acute cases in which streptomycin therapy and sulfonamide therapy were combined apparent cures were achieved. The results in acute typhoid fever were disappointing, and in 2 of 3 typhoid carriers treatment was a failure. A patient with dysenteroid paratyphoid fever recovered

promptly. The results of treatment in enteritides due to *Salmonella* and *Shigella* organisms were generally favorable, but in nonspecific ulcerative colitis they were generally undramatic, or at least equivocal. Results in infantile diarrhea, although some deaths occurred, were usually good and sometimes dramatic.

Dosage, routes of administration and similar details are discussed, and lines of future investigation are suggested.

The conclusion continues to be warranted that in infections caused by organisms susceptible to streptomycin the results of treatment are likely to be good if the drug can be brought into contact with all foci of infection. If the organisms are not susceptible to streptomycin, treatment is without value.

GOLD THERAPY IN RHEUMATOID ARTHRITIS*

JAMES S. BROWNING, M.D.,† RAYMOND M. RICE, M.D.,‡ W. VERNON LEE, M.D.,‡
AND LESLIE M. BAKER, M.D.§

INDIANAPOLIS, INDIANA

TREATMENT of rheumatoid arthritis with gold compounds, initiated in Europe twenty years ago, has gradually grown in favor in American medicine during the past ten years. Recently, Fraser¹ condensed the literature on chrysotherapy in this disease and noted that most observers report a favorable response in 70 to 80 per cent of patients. Short, Beckman and Bauer² found more than forty publications on gold therapy in the English literature up to 1946, almost all of which were favorable toward this type of treatment. Since these recent summaries are available, a review of the literature on this subject is not attempted in this report. When the publication of Short, Beckman and Bauer appeared, again raising the question of efficacy, we were engaged in reviewing six years' experience with gold treatment in the Arthritis Clinic, Indianapolis City Hospital. The results revealed in this survey seem sufficiently comparable to those reported by the Boston group to justify publication of the findings.

TREATMENT

The chronic nature of rheumatoid arthritis and its tendency to spontaneous improvement or exacerbation make difficult the accurate evaluation of progress. This is further complicated by the optimistic nature of many patients who are prone to symptomatic improvement with any treatment.

administered with a hopeful attitude on the part of the physician. Aware of its shortcomings but in the hope of providing a standard method of evaluation, we adopted a modification of the "yardstick" of Bayles and Hall.³ To illustrate the method used, a portion of one patient's record is presented in Figure 1. As indicated in the key, four objective findings—mobility, activity of disease, static deformity and extent of involvement—are translated into a numerical value. Similarly, laboratory findings and subjective symptoms are assigned a number. The total of all six items provides an index number, with which the index obtained on subsequent examinations is compared. In the estimation of progress a change of two points in the index is considered to be significant. Hence, a value that decreases from 12 to 10 is accepted as indicative of improvement, and, conversely, a change from 12 to 14 is taken as evidence of progressing disease. The method appears to be helpful in the long-term and follow-up study necessary in the evaluation of therapy.

With the use of the index system the records of 52 patients treated with gold were examined. Five of these were eliminated at the outset because the patients had received less than 100 mg. of gold salts. The records in the remaining cases form the basis for this report. All patients had a definite diagnosis of active rheumatoid arthritis. All were adults ranging in age from twenty to sixty-four years at the time treatment was begun. There were 34 women and 13 men, representing a sex ratio of a little less than 3:1. The longest period of

observation was six years, but all patients were followed for more than eighteen months. The stage of disease at the time treatment was initiated varied from less than two years' duration in 18 cases, or 38 per cent, to the later stages of the disease in 29, or 62 per cent. Patients with more advanced involvement had been treated elsewhere

was followed, with most patients receiving 50 mg of gold sodium thiomalate or 25 mg of actual gold. The total amount per course has remained at 1000 mg of the salt, but in most patients now under treatment, maintenance therapy of 25 mg every two weeks has been continued indefinitely after a course has been completed. In addition,

FIGURE 1 Reproduction of a Patient's Chart

The key is as follows:

- M — Mobility: 0 — employable; 1 — ambulatory (able to get about alone); 2 — confined to one floor, bed and chair without assistance; 3 — confined to bed needing part-time assistance (able to feed self and so forth); 4 — confined to bed needing full time assistance (helpless).
- A — Activity of disease: 0 — no activity (history of having had disease); 1 — presence of disease but no objective signs of activity at present; 2 — intermittent heat, swelling and effusions in joints; 3 — appearance of subcutaneous nodules, persistent heat, swelling, tenderness and effusions in joints with mild to moderate muscle atrophy and slow joint destruction; 4 — fulminating rapid course of disease with joint destruction, fever, rapid weight loss and so forth.
- D — Deformity of static nature (made on worst joint): 0 — none; 1 — periarticular thickening, painless fluid or crepitus on motion; 2 — limitation of motion; 3 — subluxation; 4 — ankylosis or stiff joint.
- E — Extent of joint involvement (percentage of joints involved): 0 — none; 1 — 0 to 24; 2 — 25 to 49; 3 — 50 to 74; 4 — 75 to 100.
- L — Laboratory evaluation: 0 — no abnormality; 1 — slight increase in sedimentation rate (Wintrobe method, +5 mm) or slight anemia, or both; 2 — moderate change in sedimentation rate (+10 mm); 3 — severe change in sedimentation rate (+20 mm); 4 — extreme change in sedimentation rate (+30 mm or more).
- S — Subjective symptoms: 0 — none; 1 — intermittent mild to moderate malaise, weakness, fatigue and joint pain; 2 — continuous and mild to moderate for the above symptoms; 3 — intermittent and severe or continuous and moderate for the above symptoms; 4 — continuous and severe for the above symptoms.

with the usual variety of remedies, but none had previously been treated with gold.

During the first years of chrysotherapy the customary weekly dose of 100 mg of gold salts was given to a total of 1000 mg per "course." Gold sodium thiomalate (Miochrysine) was the standard compound, although for about a year gold acetyl cystein was given. Since both compounds contain 50 per cent gold, they are considered comparable therapeutic agents. During the past four years, the current practice of giving lower weekly doses

acetyl salicylic acid has been used freely to control pain, and application of heat to affected joints has been a daily routine with the majority of patients.

RESULTS

With classification on the basis of the total amount of gold salts administered, the results of treatment are summarized in Table 1. It is interesting that 8 patients who were given only 500 to 1000 mg showed the greatest percentage improvement of any group — in fact, 17 per cent greater

than that in the group of 10 patients who were given more than 3000 mg. The next greatest improvement was in the 9 patients who received less than 1500 mg. This suggests that the first course of gold is the most effective, a finding noted by others.⁴ It is interesting that 6 of the improved patients, 5 of those in the unchanged group, and all 7 listed as failures had been victims of the disease for less than two years. With these 18 patients as a group representing the earlier stages of rheumatoid arthritis, 33 per cent were improved, 28 per cent were unchanged, and 38 per cent

The fifth patient, a forty-two-year-old woman, developed a mild dermatitis after receiving 400 mg of gold salts. This was not recognized as a toxic effect of gold, and treatment was continued. When 625 mg. had been given the patient rapidly developed exfoliative dermatitis. After five months' hospitalization for the skin condition, she died, the disease having been further complicated by epilepsy and latent syphilis. This fatal case must obviously be attributed to gold poisoning.

Evidences of gold toxicity were seen in 29 patients, or 62 per cent, of the entire group. Skin

†Patient worse after therapy

became worse with gold therapy. It is only fair to state that 62 per cent of the entire group showed no measurable change for better or for worse as a result of treatment. A possible effect of gold in preventing advance of the disease may thereby be implied.

Toxic Effects

During the six-year period 5 patients died, but only 1 fatal case seemed definitely attributable to gold toxicity. One man died at the age of sixty-seven years because of congestive heart failure three years after receiving a total of 400 mg of gold salts. A woman died at the age of forty-five years with a questionable diagnosis of amyloidosis. She had completed a course of 1150 mg of gold salts three years before death. Treatment had been discontinued because of an exfoliative dermatitis apparently due to gold, but she had recovered from this within six months after treatment had been stopped and two and a half years before death. A forty-two-year-old woman developed a mild dermatitis after having received 1215 mg of gold salts. She died three months later after surgery for acute bowel obstruction. Another woman, aged sixty-three years, had received only 95 mg of gold salts when she developed a mild purpura. Treatment was stopped, and she failed to return to the clinic. A follow-up letter six months later revealed that she had recently died, presumably of cerebral thrombosis.

reactions were observed quite frequently and were the reason for temporary or permanent withdrawal of the drug in 25 cases. In most cases only a mild pruritus or limited skin eruption was seen, and often after the skin had become normal treatment was cautiously resumed. Some of these patients were able to complete the course of therapy without further side-effects. Exfoliative dermatitis was seen in only 2 patients, and 2 others exhibited evidence of purpura. Treatment was discontinued temporarily in 2 cases because of neutropenia. Several patients showed evidence of renal irritation in the form of transitory proteinuria or microscopical hematuria. Diarrhea thought to be due to gold was occasionally observed.

DISCUSSION

In these patients treated with gold salts the results have not approached those reported in the majority of publications on this subject. An explanation may be found in the longer period during which the patients were observed. In many cases apparent improvement was seen after treatment, but in few cases was there a lasting effect. In this report no attempt has been made to discuss separately patients who improved only to relapse, for it is believed that a period of more or less temporary relief is of little consequence in this disease.

The percentage of improvement in this series happens to be the same as the 23 per cent net

improvement reported by Short, Beckman and Bauer² in 35 cases. In contrast, through the use of general and orthopedic treatment, these authors obtained improvement in 52.9 per cent of a larger series of 274 cases without the risk that is always associated with gold therapy.

SUMMARY

Forty-seven patients with active rheumatoid arthritis were observed for periods of eighteen months to six years. All received gold therapy in amounts ranging from less than 500 to more than 3000 mg of a salt containing 50 per cent gold. Those who continued in an improved state after treatment constituted only 23 per cent of the total,

whereas 62 per cent showed no appreciable change, and 15 per cent became worse.

A high incidence of toxic reactions to gold was noted, 62 per cent of patients having been involved. Although most of these side-effects were of little consequence, there were 2 cases of exfoliative dermatitis, with 1 death.

TREATMENT OF ACUTE UREMIA BY PERITONEAL LAVAGE

Report of a Case

MAJOR ROBERT W. BUCKLEY, MC, AUS, AND CAPTAIN ROGER A. SCHOLTEN, MC, AUS

THE treatment of uremia has long been directed toward symptomatic relief, healing of the underlying renal lesion and in acute and presumably temporary cases, maintenance of life long enough to allow the kidneys to reassume their essential functions. It is toward the last objective that attempts have been made by numerous workers to supply a temporary "substitute" for the kidneys, which would maintain excretion of uremic metabolites, whose retention is fatal to the organism. In a review of the chemical changes known to occur in uremia, Harrison and Mason¹ stressed the importance of increased blood and tissue concentrations of urea, free phenols and guanidine-like substances, the depression of ionized-calcium concentrations through the accumulation of phosphate, citrate and oxalate, the debilitating effects of water and chloride deprivation, particularly on tissue proteins, the profound disturbances in acid-base balance due to loss of sodium ions and accumulation of organic and inorganic acids, and the hypothetical toxic effects of many other retained substances as yet incompletely identified. Since theoretically modifications in the equilibria of all the substances named above might be effected by indirect contact, through a semipermeable membrane, with a solution of different composition, repeated experiments have been made to bring the circulating blood of uremic organisms into such osmotic contact with a prepared solution.

The technic of removal of diffusible substances from the circulating blood by dialysis through a celloidin membrane surrounded by various solutions of crystalloids was successfully demonstrated in 1912 by Abel, Rowntree and Turner² and reported in detail in 1914. In the experiments performed, meas-

urable amounts of nonprotein nitrogenous substances were removed from the circulating blood of normal rabbits, and orally administered salicylates were recovered from the blood of dogs. In 1923 Ganter³ reported the use of the peritoneum in human beings as a "natural" semipermeable membrane, a hypotonic solution being introduced into the abdominal cavity in an attempt to remove uremic substances from the blood. In a patient with chronic nephritis this attempt at maintaining life was unsuccessful. Thereafter, Rosenak and Siwon,⁴ von Jenv,⁵ Balazs and Rosenak,⁶ Bliss, Kastler and Nadler,⁷ Haam and Fine,⁸ Seligman, Frank and Fine⁹ and Abbott and Shea¹⁰ demonstrated, in mammals rendered uremic by nephrectomy or ureteral ligation, that significant amounts of "uremic substances" could be removed from the circulating blood with temporary prolongation of life. The method generally used was intermittent injection into and withdrawal from the peritoneal cavity of various solutions approximating the crystalloid content and reaction of intercellular fluid. In a study of various solutions by Abbott and Shea¹⁰ the most satisfactory fluid for use in dogs rendered uremic by bilateral nephrectomy was found to be Hartmann's solution with added sodium bicarbonate, monosodium phosphate, magnesium chloride and dextrose in concentrations up to 5 per cent.

Following Ganter's³ effort to relieve uremia in a human patient by peritoneal dialysis, several attempts were made by Heusser and Werder,¹¹ Balazs and Rosenak,⁶ Wear, Sisk and Trinkle,¹² Rhoads¹³ and Fine, Frank and Seligman,⁹ "who used various modifications in solution and technic of perfusion of the peritoneal cavity. Of the 17 patients whose cases are known to have been reported prior to the

present communication, only 2 have survived peritoneal dialysis. One was a case of "reflex anuria," with bladder calculus reported by Wear et al¹² in which the nonprotein nitrogen was never above 71 mg per 100 cc, and the alkali reserve was 51 vol per cent. Since the bladder obstruction was relieved by catheterization and suprapubic cystotomy with subsequent profuse diuresis, the role of peritoneal dialysis was less clear cut in this case than in other reported cases. The other successful case reported by Frank, Seligman and Fine¹⁵ was elsewhere compared with 3 cases treated by the same authors in which death followed the procedure.¹⁴ This case was that of a fifty-one-year-old man with acute sulfathiazole anuria and uremia who recovered kidney function after seven days of continuous peritoneal irrigation with modified mammalian Tyrode's solution, in addition to the usual supportive measures.

The patient in the following case was treated through the courtesy of Drs Frank and Seligman, of the Beth Israel Hospital, Boston, who made available all necessary apparatus and technical data and offered invaluable advice in the conduct of therapy.

J A Y, a 37-year-old single military prisoner was admitted to an Army hospital on July 8, 1946, complaining of burning abdominal and chest pain and hemorrhage by mouth, rectum and urethra, of about 3 hours' duration. A history was subsequently obtained that the soldier had been absent without leave and drinking heavily, with a markedly inadequate diet, for about 1 month and that, because of an acute situational depression, he had taken seven tablets (3.5 gm) of mercuric chloride by mouth in a suicidal attempt. Within 30 minutes he had begun to vomit a bright, bluish-green liquid containing no undigested tablets, he was transferred to the hospital after routine emergency treatment with milk and egg white by mouth.

The family and past histories were noncontributory. Psychiatric examination throughout the hospital stay showed the patient to be emotionally unstable and immature, but not psychotic.

Physical examination revealed a well developed and well nourished man who appeared pale, prostrated and acutely ill and who was vomiting gross blood. The skin was dry, loose and sallow. There were areas of alopecia over the parietal areas of the scalp due to pre-existing fungus infection. The conjunctivas and pharynx were moderately injected. The heart and lungs were normal except for a soft systolic apical murmur, the blood pressure was 122/88. The abdomen was tense, tender and slightly distended, with marked peristaltic activity audible to the naked ear. No organs or masses were felt, owing to the marked abdominal tenderness and spasm, but on the 2nd hospital day the liver was palpated two and a half fingerbreadths below the right costal margin. There was no peripheral edema, neurologic examination was essentially negative.

Examination of the blood disclosed a red-cell count of 5,500,000, with a hemoglobin of 17.5 gm, and a white-cell count of 9850, with 89 per cent neutrophils, many of which showed toxic granulation. A specimen of urine measured 100 cc. and was grossly bloody, and gave a +++ test for albumin and a + test for sugar (following intravenous injection of glucose), the sediment was filled with degenerated red cells. The nonprotein nitrogen was 40 mg per 100 cc., and the carbon dioxide combining power 46 vol per cent. A Gettler test on the vomitus and the urine showed traces of mercury.

Eight hours after the initial ingestion of mercuric chloride — during which the patient had been given milk, cream and egg white by mouth, 2000 cc. of 5 per cent glucose in physiologic saline solution and distilled water and 1 gm of sodium

thiosulfate intravenously — a supply of BAL in oil (Dimer captopropanol, United States Army Medical Department Item 1088500¹⁶) had been obtained. The patient was given 10 per cent BAL in oil intramuscularly in the dosage recommended by Eagle and Longcope¹⁷ 350 mg initially, 175 mg 2 hours later, 175 mg 4½ hours after the second dose and 175 mg at decreasing intervals for the next 4 days. He experienced a severe subjective reaction to the first injection, with headache, dryness of the lips, constriction of the chest, burning of the urethral meatus and transitory elevation of the blood pressure to 144/110. Thereafter, there was little or no subjective reaction to the injections. Within 48 hours hematemesis had ceased, and the small, frequent stools appeared to contain old, rather than fresh, blood.

During the first 12 hours in the hospital, the patient passed a total of 110 cc. of grossly bloody urine, thereafter, he passed no urine until the 7th hospital day. He was more comfortable but developed increasing azotemia, so that on the 4th hospital day, the nonprotein nitrogen was 109 mg, the blood urea nitrogen 67 mg, the serum sodium 370 mg, and the total protein 6.5 gm per 100 cc., the carbon dioxide combining power was 40 vol per cent. The cephalin-flocculation test (Hanger) was ++++ in 24 hours.

On the 5th hospital day — the 4th day of complete anuria — continuous peritoneal lavage was instituted with modified Tyrode's solution containing 2 per cent glucose, 2.9 per cent sodium bicarbonate and effective concentrations of heparin, penicillin and streptomycin. Small parallel incisions were made on the right and left lateral aspects of the abdominal wall at the level of the umbilicus, one was fitted with a stainless-steel, blunt-tipped suction nozzle for inflow, and the other with a large stainless-steel sump drain inserted well down into the pelvis, with a loosely fitting, straight suction tube laid inside the sump. Grossly bloody abdominal fluid, which gave a negative Gettler reaction for mercury, was recovered through both incisions.

The inflow and outflow tubes were fitted into the continuous-flow and suction apparatus described by Frank et al,¹⁴ and as much perfusing fluid as possible was run through the abdominal cavity, depending on the rapidity with which the suction apparatus could withdraw fluid and prevent painful distention. For the first 2 days of lavage flow was satisfactory, reaching a maximum of 30 liters in the second 24 hours. Thereafter, because the patient tampered with the dressings, the inflow and outflow tubes and the regulating clamps, satisfactory perfusion was never maintained. The highest subsequent daily total was 23 liters on the fifth day, other daily rates varied from 3 to 14 liters. Peritoneal lavage was maintained as steadily as possible for 12 days, since by that time no free fluid could be aspirated through the blocked suction tube, even after removal and cleaning of the tube, lavage was discontinued.

Throughout the hospital course, supportive treatment was given with intravenous fluids, frequent transfusions and the supplementary vitamins B, C and K parenterally. On the 6th hospital day a few coarse rales appeared over the left posterior lung base, the temperature gradually rose to 100°F. Penicillin given intramuscularly in doses of 20,000 units at 3-hour intervals, followed by streptomycin in doses of 0.1 gm, administered every 3 hours with the penicillin injections, caused gradual defervescence after the 11th hospital day. The patient was given deep breathing and coughing exercises, and the basal rales gradually diminished. No significant organism was found in the sputum except an apparently air-borne yeast, which was also growing in the outflow bottle of the peritoneal lavage. On the 10th hospital day, because of increasing abdominal distention and decreasing audible peristalsis, a Miller-Abbott tube was passed, this effected gradual decompression, but on the 18th hospital day the patient, while momentarily unobserved, pulled out the tube and shortly thereafter vomited small amounts of blood.

The patient voided 50 cc of clear urine on the 7th hospital day, 32 cc. on the 9th day, and daily increasing amounts thereafter, to a maximum of 910 cc. on the 26th day. The urea nitrogen content of this urine, however, never became higher than 300 to 400 mg per 100 cc., which was grossly inadequate to maintain nitrogen balance. The outflow from the peritoneal lavage contained urea nitrogen in concentrations roughly equal to those of the blood, no other chemical determinations were done on the fluid. The blood nonprotein nitrogen, which had risen to 109 mg per 100 cc. before peritoneal lavage, remained in the vicinity of 100 mg until

the 11th hospital day, when it again rose precipitantly to 150 mg per 100 cc. The blood urea nitrogen at that time was 105 mg per 100 cc., the carbon dioxide combining power had remained between 20 and 40 vol. per cent by virtue of daily intravenous administration of 1/6 molar sodium lactate. When peritoneal lavage was completely discontinued azotemia increased still more rapidly; on the 25th hospital day the nonprotein nitrogen was 365 mg, the serum sodium 473 mg., and the potassium 21.4 mg per 100 cc. and the carbon dioxide combining power 33 vol. per cent.

On the 22nd hospital day the patient developed edema of the sacrum, scrotum and ankles; further edema was forestalled by reduction of intravenous fluid to 1500 cc. daily. He rapidly failed, with increasing drowsiness, continuing abdominal distention and a temperature of 97°F. On the 23rd hospital day a much louder apical systolic murmur was heard, no friction rub was made out at any time. From the 24th day onward the patient vomited and defecated fresh blood, and on the 26th day he appeared irrational. On the 27th day he suddenly became cyanotic while sitting up in bed and died.

Autopsy. At post mortem examination performed by Major Samuel Berg 6 hours after death, the abdomen was distended, there were recent surgical incisions from the insertion of tubes for peritoneal lavage. There was mild generalized edema, most marked over the prethoracic regions. The greater omentum was attached to the abdominal wall and underlying viscera by many adhesions varying from thin to firm fibrous bands. There was a large quantity of blood-tinged peritoneal fluid containing flakes of fibrin. Between many coils of intestine there were pockets of thick, yellow, odorless pus which on culture showed colonies of *Escherichia coli* and of *Monilia*. There was a well advanced "bremic pericarditis," with fibrinous adhesions and 30 cc. of blood-tinged pericardial fluid.

The right lung weighed 750 gm. and the left 450 gm. The bronchi were congested; there was moderate pulmonary edema, most marked in the lower lobes. There were several isolated thick walled small abscesses.

The heart weighed 490 gm., the musculature was extremely flabby. Measurements of the valves were within normal limits. The thickness of the left ventricle was 18 mm. About the chordae tendineae of the posterior cusp of the mitral valve there was a firm constricting—apparently ante-mortem—clot, with a pencil-sized tail extending upward through the aortic valve.

The spleen was normal except for mild congestion. The liver weighed 2700 gm., and was softer than normal in consistency. The pancreas was embedded in a mass of fragile fatty material. The entire lesser peritoneal sac contained 60 cc. of turbid brown fluid, with soft, whitish flakes.

Examination of the gastrointestinal tract revealed a plastic brown exudate over the posterior wall of the stomach, a perforation of the stomach had apparently occurred and had subsequently been walled over by exudate. There was marked hemoglobin staining of the mucosa of the entire intestine, the mucosa was thin and there were numerous necrotic transverse ulcerations throughout the distal duodenum, proximal jejunum and the entire colon. From the position of the ulcers and the nearby peritoneal abscesses, it was the opinion of the pathologist that perforation of the intestine had occurred in several places.

The right kidney weighed 420 gm., and the left 460 gm. When each kidney was transected the parenchyma bulged high above the cot edge of the capsule. Both kidneys were pale throughout, the glomeruli could not be visualized grossly.

The brain weighed 1270 gm. and was grossly normal. Microscopical examination disclosed that some alveoli of the lungs were partly collapsed; others showed emphysematous distention. The alveolar capillaries were markedly distended and in sections from the lower lobes, the alveoli contained moderate numbers of erythrocytes and pigment-bearing phagocytes, as well as some small, round cells. There was marked disparity in the size of the cell nuclei of the liver. The cytoplasm was finely granular, and in places there were large, round vacuoles suggesting fatty degeneration. Many of the hepatic cells and a few of the Kupfer cells were almost filled with light-brown pigment granules. There were moderate numbers of small round cells about the bile ducts and in foci in the capsule of Glisson. There was extensive necrosis of the peripancratic tissue, without changes in the pancreatic tissue itself.

The glomerular tufts of the kidneys were anemic and showed edema and desquamation of the capsule epithelial cells but were otherwise normal. The tubules showed marked changes, with no uniformity from place to place. The epithelial cells were loosely attached to the basement membrane, with some cells lying free in the lumens. Some of the tubules singly and in groups, showed marked atrophic changes, the few epithelial cells lying haphazardly in clusters within an edematous stroma containing small round cells and a few polymorphonuclear leukocytes. In a few places in the distal tubules on the other hand, the epithelial cells were stratified and the nuclei varied in size, suggesting recent regeneration.

In this case peritoneal lavage was used in an attempt to maintain life for a sufficient period to allow restoration of kidney function after sudden failure. Despite survival for twenty-seven days, it is evident that sufficient kidney function had not been restored in that time to sustain nitrogen balance unaided, since although a urinary volume of 910 cc was achieved on the last day of life, there was not adequate concentration to ensure removal of large amounts of uremic metabolites from the body. It is certain, however, that the procedure of peritoneal lavage prolonged the patient's life at least ten to fourteen days beyond the expected survival period in complete anuria. Despite the optimistic figures given by Eagle and Longcope,¹⁷ treatment with intramuscular BAL did not appear to effect significant detoxification of the ingested mercury, since the drug could not be obtained until eight hours after the onset of poisoning, it is possible that administration at an earlier time in the illness would have been more effective.

The difficulty in maintaining free flow in peritoneal lavage in this case is best explained, in retrospect, by the supervention of sepsis and adhesions in the abdomen. It is believed that the patient's lack of co-operation in tampering with the apparatus and skin incisions had much to do with this situation, the likelihood of air-borne contamination around the outflow suture, the undecided influence of intestinal perforation and the ever-present possibility of contamination during manipulations of the apparatus, which were not carried out under operating-room asepsis, must also be borne in mind. Again, the patient's summary removal of the Miller-Abbott tube undoubtedly aided in increasing intra-abdominal pressure, which constituted another interference with free intraperitoneal flow.

On the basis of this experience it seems that peritoneal infection is a danger that, as stated by other authors, must be taken into consideration but need not be considered a barrier to institution of this therapy in cases that can be suitably controlled. On the contrary, the survival of this anuric patient for twenty-seven days is regarded as an encouraging result pointing to a better prognosis in similar cases handled with improved technique.

SUMMARY

The literature pertaining to treatment of acute uremia by peritoneal lavage is reviewed.

A case is reported in which continuous peritoneal lavage for twelve days resulted in survival for twenty-six days after complete renal shutdown due to mercuric chloride poisoning.

The importance of avoiding peritoneal infection in this procedure is stressed, but further evidence is added for the growing opinion that "substitution" for the nonfunctioning kidneys in acute uremia is a practicable and useful procedure.

MEDICAL PROGRESS

HEMATOLOGY*

WILLIAM DAMESHEK, M.D.†

BOSTON

THIS report covers recent progress in the investigation and treatment of the anemias and the hemorrhagic diseases.

ANEMIAS

As in previous progress reports, the anemias are classified primarily on etiologic grounds. Such a classification is simple and easily remembered and may be said to be based on economic principles: the bone-marrow "factory" requires materials for the production of its most important finished product, the red cell. Anemia results when the materials necessary for supplying the bone-marrow factories are inadequate, the factories themselves are inadequate or there is an excessive loss either by hemorrhage or by increased breakdown of the finished product, the red cell. Stated in more conventional scientific terms the anemias may be classified as due to deficiency of materials, bone-marrow disturbances and excessive blood loss, whether hemorrhagic or hemolytic.

Deficiency Anemias

Folic acid. The outstanding advance of the year is undoubtedly the advent of folic acid as a therapeutic agent in deficiency syndromes associated with macrocytosis of the red cells.

The devious routes by which folic acid came into being as a drug that the medical practitioner could use in his daily practice are fully described in a comprehensive article by Berry and Spies.¹ The apparently dull and impractical researches of bacteriologists, nutritionists, chemists and other "pure" scientists finally led to the development of a highly potent agent that, in a dosage of a few milligrams a day, was sufficient to result in remissions in pernicious anemia, sprue and related conditions.

The lowly bacterium, more particularly the *Lactobacillus casei*, provided the test subject for various growth factors, which could then be methodically studied. Snell and Peterson² found that these bacteria required extracts of plants or animals for proper growth. Yeast extract and certain fractions of liver extract were both rich sources of the essential growth factor, or the *L. casei* factor as it came to be called. Patient fractionation finally yielded a relatively simple material that was present in high concentration in spinach, a leafy vegetable—hence the term "folic acid." The pure compound was seventy-five to one hundred and thirty-seven thousand times as active as a standard liver fraction.

Since 1932 Wills and Bilimoria³ had been working on a type of anemia that could be produced in monkeys by a diet similar to that consumed by

*From the Blood Laboratory of the Joseph H. Pratt Diagnostic Hospital, Boston Dispensary, and the Department of Medicine, Tufts College Medical School.

†Professor of clinical medicine, Tufts College Medical School; hematologist, Joseph H. Pratt Diagnostic Hospital.

certain Indian natives. This anemia, which was macrocytic in type, could be prevented or cured by a crude autolyzed yeast extract or by Cohn's liver extract, fraction G. The exact vitamin responsible could not be determined but was called vitamin M. When the *L. casei* factor became available, it was used in the deficient monkeys and resulted in a dramatic return to normal of all evidences of the deficiency state, including the abnormal blood picture. Other investigators, often working in large teams (fifteen authors are listed in one article), attacked the problem of certain deficiency states in chicks in which a macrocytic hyperchromic anemia was present.⁴ Prevention and cure of this deficiency was finally achieved by a fraction of the vitamin B complex. The exact nature of this material, which was called the vitamin B₁₂ factor (vitamin B₁₂, chick factor) could not at first be determined, but work by other groups demonstrated that effects identical with those induced by the vitamin B₁₂ factor could be duplicated by the use of the *L. casei* factor. Conversely, the vitamin B₁₂ factor replaced the *L. casei* growth factor in experimental work with *L. casei*. Synthesis of the material, which was called pteroylglutamic acid, was finally achieved by a group of chemists working in the Lederle Laboratories,⁴ and it was then determined that this new compound was equally effective in the deficiency anemia of chicks, the M deficiency state of monkeys and the *L. casei* nutritional deficiency of bacteria.

The folic acid material, which was extracted from previously discarded liver-extract residues, was chemically analyzed and later synthesized and was then supplied to a number of investigators interested in nutritional problems. Among these was Spies,⁵ whose investigations in pellagra and in other deficiencies involving the vitamin B complex had been outstanding. Spies and his collaborators had previously tried, with relatively little success, fractions of the vitamin B complex in certain cases of anemia, which were usually of the macrocytic type. With the use of the newly synthesized folic acid striking clinical and hematologic effects were obtained.⁶⁻¹¹ The hematologic response, which was considered to be identical with that found in pernicious anemia when liver extract was given, showed a reticulocytosis with a subsequent rise in red cells, hemoglobin and leukocytes. These results were quickly confirmed by various observers, including Moore and his associates,¹² who reported clinical and hematologic remissions in 2 patients with pernicious anemia after the daily oral administration for ten days of 30 mg and 100 mg, respectively, of the synthetic material. A patient with the macrocytic anemia of nontropical sprue and another with pernicious anemia of pregnancy responded similarly when given the material intravenously in a dosage of 20 mg. Zuelzer and Ogden¹³ showed that folic acid was also effective in the treatment of the

megaloblastic anemia of infancy. These cases, which presented pallor, vomiting, fever, slight cardiac enlargement and, at times, splenomegaly, demonstrated a normochromic, macrocytic blood picture and a megaloblastic bone marrow. Folic acid resulted in reticulocytosis, erythrocytosis and a return of the bone marrow to normal.

Numerous reports have since appeared from various parts of the country and have shown conclusively that 5 to 20 mg of folic acid given orally as a daily dose is sufficient to induce a well marked, often maximal, reticulocytosis and a well defined, if not maximal, erythrocytosis. Simultaneously, striking responses take place clinically. It is not yet completely settled whether folic acid causes consistently maximal responses in erythrocytes similar to those produced by liver extract, or whether folic acid alone prevents or improves the neurologic lesions of pernicious anemia. More theoretical questions are discussed below. Watson and Castle¹⁴ demonstrated the effectiveness of a material other than pure liver in certain cases of "nutritional macrocytic anemia," especially in pregnancy. These cases had failed to respond to the parenteral administration of refined liver extract in doses ordinarily sufficient to induce a remission in ordinary cases of pernicious anemia, but when a crude oral extract of liver (Valentine) was given, excellent responses occurred. Unfortunately, sufficiently large doses of folic acid were not given to these patients to determine whether they would have responded to this medication. The observations are nevertheless of great importance as indicative of the fact that nutritional macrocytic anemias may be of various types, some responding to pure liver extract, some responding to folic acid but not to pure liver extract, and some responding to either material (and perhaps some responding to neither).

Spies and his co-workers demonstrated that folic acid was effective in all the deficiency states associated with a macrocytic anemia. These included not only pernicious anemia but also certain cases of vitamin B complex deficiency. Sprue seemed to be a condition in which this material could well be effective. The favorable response of a few cases of nontropical sprue to folic acid had already been noted by Moore et al.¹² and by Darby and Jones.¹⁵ In Cuba, Spies and his associates⁹ quickly collected a group of cases of tropical sprue treated with folic acid. Preliminary observations by Spies and his co-workers⁹ and later by Spies and Suarez¹⁶ in Puerto Rico demonstrated that small doses of material (5 to 15 mg daily by mouth) usually resulted in dramatic clinical and hematologic improvement, this was often far greater than that obtained by the use of large doses of crude liver extract in association with a well balanced diet.

The synthesis of folic acid was a difficult chemical task and was undertaken by a large group of

chemists working in the Lederle Laboratories. Although synthesis was first announced in 1945, the actual details of chemical identification and methods were kept secret until approximately a year later, when a publication by Angier and his collaborators⁴ appeared. Chemically, folic acid consists of a substituted pteridine combined with a molecule of para-aminobenzoic acid and a molecule of glutamic acid to which the name "pteroylglutamic acid" was applied.

The theoretical aspects of folic acid therapy resulted in a whole new set of problems to plague the investigator especially at a time when it seemed that the problem of pernicious anemia was to a great extent solved or at least quiescent. The response to two entirely different substances is puzzling. Castle's theory of the interaction of an "extrinsic" factor in the food with an "intrinsic factor" in the gastric juice leading to the development of a "liver-extract factor" or an "erythrocyte-maturation factor" is by no means invalidated. Folic acid appears to be neither the extrinsic nor the intrinsic factor. Heinle¹⁷ discusses these theoretical matters at length. On the basis of preliminary experimental data, he concludes that a "principle of liver extract, possibly the antipernicious anemia factor is concerned with the release of free folic acid from conjugates of the vitamin." This would, of course, explain the identical action of two distinctly different substances, patients with pernicious anemia, although they might possess adequate amounts of conjugated folic acid would find it of little value because free folic acid could not be liberated. Liver extract apparently releases this material from the conjugated substance, and folic acid, of course, supplies it ready made. In a review of the clinical and experimental aspects of folic acid, Doan^{18, 19} makes the point that this material is essential for normal cellular metabolism, lacking it, the marrow becomes defective with resulting pernicious anemia. Perhaps to confuse the picture even more for the ordinary reader is the report by Spies and his co-workers^{20, 21} on the antianemic properties of thymine. This material, which is derived from thymonucleic acid, was also effective (in massive doses of 4.5 to 15 gm daily) in causing remissions in pernicious anemia. The relation of this material to folic acid is quite obscure, although Spies and his collaborators suggest that the latter substance acts as an enzyme or coenzyme in the synthesis of thymine or a thymine-like material.

Other aspects of pernicious anemia. The following papers deal with didactic matters that, in comparison with the dramatic events relating to folic acid therapy, seem relatively dull. Schwartz and Rappolt²² report 3 cases of pernicious anemia in Chinese hospitalized at the Cook County Hospital. Another case in a Chinese is reported by Hartwell²³ from Honolulu. The occurrence of carcinoma of the esophagus in a long-established case of perni-

cious anemia is described by Cooke,²⁴ and that of leiomyosarcoma of the stomach by Schindler and his associates.²⁵ Typical examples of the disease occurring in children are described by Jonssen²⁶ and by Peterson and Dunn,²⁷ as well as by Zuelzer and Ogden.¹³ The following criteria should be present: macrocytic anemia, histamine-resistant achlorhydria, megaloblastic marrow, reticulocytosis after liver-extract therapy and necessity for continued administration of liver extract. The occurrence of pernicious anemia in association with intestinal strictures and anastomosis is discussed by Richardson,²⁸ who believes that a stagnant intestinal loop, by causing damage to the intestinal mucosa, helps to bring about the disease. A likelier explanation is that malabsorption of the liver-extract factor results in a conditioned deficiency of this substance.

Cayer, Ruffin and Perlzweig²⁹⁻³¹ studied the levels of various vitamins in the disease. Those of vitamin A and pyridoxin were within normal limits in all patients, but those of niacin (nicotinic acid), riboflavin and thiamine were below normal. The authors concluded that, if liver extract alone does not result in a completely adequate response in pernicious anemia, components of the vitamin B complex should be given. (This is even more applicable to folic acid, a fraction of the vitamin B complex.)

Liver-extract sensitivity not infrequently develops in the course of parenteral therapy. In a large series of cases treated at the Cook County Hospital in Chicago, Schwartz and Legere³² found that 17 per cent of patients developed manifestations of sensitivity including itching, flushing, tachycardia, asthmatic reaction or even shock. Treatment of this sensitivity is relatively easy in most cases and consists in a change of the brand of extract, particularly to one in which beef liver is used instead of the pork product, reduction of the dose of material and desensitization, which is often unsatisfactory. In stubborn cases Schwartz suggests the use of a histamine protein complex to produce antihistamine antibodies, with the use of this "anti-H" material* good results were obtained in 10 of 11 cases. Folic acid has naturally revolutionized the treatment of desensitization.

The neurologic complications of pernicious anemia are in some ways far more important than the hematologic — and far less readily controlled. Although disorders due to disturbances of the posterolateral column of the spinal cord are best known, Rundles³³ points out that three other types of involvement may occur: cerebral, olfactory and that of the peripheral nerves and nerve roots. Olfactory symptoms were found in 4 of 20 cases, perversion or loss of taste for foods, especially for proteins, occurred independently of atrophic or inflammatory changes of the lingual mucosa. Eleven of the 20 patients had involvement of the peripheral nerves.

*Obtainable from Parke, Davis and Company of Detroit

as well as of the posterior columns of the spinal cord. Foster³⁴ also points out the importance of peripheral-nerve involvement in pernicious anemia. Although it is clinically difficult to distinguish involvement of the posterior column from that of the peripheral nerve, it is essential to give maximum therapy, since peripheral nerves have a marked regenerative capacity and may thus be influenced by treatment.

Large doses of liver extract are recommended to combat the neurologic disorder, 30 to 60 units of concentrated extract being given weekly by parenteral injection until a maximum neurologic response has been obtained. Although the degree of remission cannot be foretold, one can be certain that with the continued use of about 15 units of extract every ten to fourteen days, no neurologic relapse will occur.

Iron-deficiency anemia. Schwartz and Flowers³⁵ describe the changes in the blood that occur in the course of gradually developing chronic iron deficiency, usually owing to chronic bleeding. There is a linear fall in the hemoglobin, with the red-cell count constantly lagging behind and resulting in an ever-decreasing color index. As this diminishes, characteristic changes in the red cells develop: microcytosis, hypochromia, anisocytosis and poikilocytosis. Recognition of the iron-deficiency state is important, since liver extract is of no value. Although therapy with iron salts may be effective, a search for an etiologic factor must be made. Goetsch, Moore and Minnich³⁶ describe the effects of massive doses of iron intravenously in patients with hypochromic anemia. Although the reticulocyte response is often higher and the average rate of hemoglobin regeneration greater than with oral therapy, toxic reactions are frequent and severe and thus militate against the use of this therapy in clinical practice.

The use of molybdenum in combination with iron in the treatment of iron deficiency is described by Neary³⁷ and Healy³⁸. Molybdenum, a so-called "trace element," was first used in the milk-induced anemia of rats. Neary studied 22 patients with iron deficiency of pregnancy, of whom half received ferrous sulfate alone, and half molybdenum ferrous sulfate. The patients receiving the latter combination showed a more rapid therapeutic response. Healy stated that the response to molybdenum was striking, with an average daily increase in hemoglobin of 0.36 gm per 100 cc, whereas with iron alone, in comparable cases, the average increment was only 0.12 gm per 100 cc. The results in both these papers are subject to further critical evaluation.

Schulze and Morgan³⁹ found that the addition of ascorbic acid to iron was valueless in the therapy of iron-deficiency anemia of children. It may be added parenthetically that in the presence of a state of iron deficiency, iron alone is usually all that is required for therapy. It is highly questionable whether liver extract, folic acid, copper, molybdenum and vitamins of various types do anything

except add to the cost of the preparation. Another more serious danger in the treatment of iron deficiency results from the treatment of the anemia as such, rather than finding out, first of all, what the underlying cause may be. I have seen a number of cases of hypochromic anemia in which prolonged therapy (usually with liver extract) was given but in which examination of the stools later demonstrated strong reactions for occult blood and x-ray films of the gastrointestinal tract demonstrated a bleeding lesion, usually cancer. In every case of hypochromic anemia of obscure etiology, it is imperative to search for a bleeding lesion. Diaphragmatic hernia is occasionally found, as pointed out by Chevallier and Danel.⁴⁰ These authors, however, suggest that the anemia is due to an inflammatory disturbance of the gastric mucosa. In the cases that I have observed, occult blood has always been demonstrated, provided enough stools were examined. In some cases brisk or constant bleeding is present.

Bone-Marrow Anemias

Bone-marrow disturbances are usually associated with a pancytopenia—that is, reduction in red cells, white cells (granulocytes) and platelets. They are brought about by diminished growth in the marrow (hypoplasia or aplasia), by foreign-tissue infiltration or proliferation (leukemia, neoplasm or sclerosis) or by splenic inhibition in certain conditions, usually splenomegaly.

Aplastic and hypoplastic anemia. Quinacrine (Atabrine) as a possible cause of various types of bone-marrow disturbances was suspected during the war, but for obvious reasons such suspicions were not publicized. Custer⁴¹ reports 57 cases of aplastic anemia in soldiers from the Pacific and the China and India-Burma theaters. Although the Army personnel in these areas was only one twentieth to one seventh of the total troop strength, two and a half times as many cases of aplastic anemia appeared as in soldiers from the European Theater. Quinacrine was used by a large portion of the personnel in the Pacific and the China and India-Burma theaters, and, in addition to anemia, dermatitis, weakness and hemorrhagic disturbances were noted. Most and Hayman⁴² report a single case of quinacrine aplastic anemia. A report by Greenfield⁴³ on aplastic anemia that was thought to be due to a "rifle-bore cleaner" is of interest in that quinacrine had also been used by the patient.

New medications containing the benzene ring suggest new causes for aplasia or hypoplasia of the bone marrow. Tridione, which was recently introduced as an anticonvulsant drug, has been implicated in cases reported by Harrison, Johnson and Ayer⁴⁴ and by Mackay and Gottstein.⁴⁵ Other chemical agents recently implicated in the production of aplastic anemia include the sulfonamides (Denny and Menten⁴⁶), trinitrotoluol (Sievers,

Stump and Monaco^{47, 48}), Stovarsol (Schrire⁴⁹), calcium bisulfite (Carlson⁵⁰), estradiol benzoate — estrogen (Chevallier and Umdenstock⁵¹) and benzene (Aubert⁵²). Although some of the reports are not convincing regarding a direct relation of the chemical to the aplasia, it is important to record even possibilities, since this is a chemical age and potentially dangerous materials must be guarded against. It should also be pointed out that some cases of aplastic anemia, particularly in children, are probably largely congenital in origin and become definitely evident only after a drug such as sulfadiazine has been given. The Nagasaki and Hiroshima atomic bomb explosions led to countless cases of radiation sickness. Death followed in most cases, but patients who were relatively slightly affected developed varying degrees of bone-marrow involvement. One of the first articles on this subject dealing principally with the clinical effects noted is that of Timmes.⁵³ Pancytopenia was present in most cases but in others "selective" cytopenias were present, including extreme granulocytopenia, thrombocytopenia and anemia. Lack of facilities made therapy difficult, thus, only rare cases received transfusions of blood and penicillin. Hemorrhage from lack of platelets and uncontrolled infection from agranulocytosis were frequently observed. In the mildest cases the patients recovered. It will be of interest for future investigation to note whether leukemia or other leukocytic proliferations occur in greater incidence in persons exposed to the atomic bomb than in other groups. The therapy of aplastic anemia is extremely difficult and often of no avail. Folic acid has been used by Denny and Menten⁴⁸ and by Peat⁵⁴ with questionable results. I have seen favorable results from splenectomy in the congenital hypoplastic anemia of children, and this procedure should be seriously considered, particularly if megakaryocytes are not completely lacking. Splenectomy apparently removes a normal inhibitory or regulatory influence on the bone marrow and thus allows more marked red-cell, white-cell and platelet production to take place than would otherwise occur.

Anemias Associated with Increased Blood Destruction

The anemias of increased blood loss may be either hemorrhagic or hemolytic. The former are of chief importance from the standpoint of diagnosis, particularly in the presence of continued slight bleeding from the gastrointestinal tract. The latter anemias are assuming an ever-increasing significance as more and more cases are being recognized. They may be classified as follows: the familial and hereditary, including the spherocytic, target-oval (Mediterranean) and target-sickle (sickle-cell) types, the acquired, comprising the acute, subacute and chronic, those caused by infections, chemicals, toxins and parasites (of known etiology), those associated with leukemia, lymphoma, Hodgkin's disease and

so forth (symptomatic), those associated with iso-antibodies, such as hemolysins and agglutinins and the hypersplenic type, and the hemoglobinurias.

Familial types. The familial and hereditary hemolytic anemias are for the most part readily differentiated according to the predominating type of red cell picture. The spherocytic type is the best known and is associated with the presence of small, thick dense-appearing red cells, which have an increased fragility in solutions of hypotonic sodium chloride. Several investigators have shown that the red cells of this disease have a diminished life span in a normal circulation, when the spleen is removed, the life span of the spherocyte is normal. The cause of the spherocytosis is unknown. Most authorities consider that the spherocyte is produced by an abnormally functioning marrow. This reasoning is confirmed by two findings: blood introduced into the circulation in a case of familial spherocytosis survives at a normal rate — that is, there is no vascular hemolytic factor, and tests of the red cells with an antiglobulin serum (Boorman, Dodd and Loutit⁵⁵) fail to show the presence of adsorbed antibody. Dameshek and Schwartz,⁵⁶ on the other hand, contend that since spherocytosis can be experimentally produced and since this abnormality indicates a red cell in the process of hemolytic destruction, a hemolytic substance is somewhere present, whether demonstrable or not. They cite other evidence. It is also possible that hemolysin or agglutinin is specific for the patient's own cells and thus does not cause increased destruction of introduced red cells. These hypotheses are being studied. The hemolytic crisis, which is associated with greatly increased spherocytosis and which may develop at any time in the course of the disease, may indicate an extrinsic factor or an accentuation of the already existing cause of the spherocytosis. Familial crises are reported by Horne et al.⁵⁷ and have previously been observed by Dedichen⁵⁸ and Dameshek.⁵⁹ In the cases presented by Horne and his associates the red cells contained peculiar inclusion bodies that were perhaps related to Howell-Jolly bodies.

The various clinical types of the target-cell and oval-cell syndromes, which occur primarily in persons of Mediterranean ancestry, have been reported by Dameshek.⁶⁰ All cases show target, oval and stippled cells and increased hypotonic resistance of the red cells. A typical mild case with hypochromic erythrocytosis occurring in a Chinese is reported by Greenblatt, Cohn and Deutsch.⁶¹ Stiles, Manlove and Dangerfield⁶² presented a characteristic case in a Negro in whom there was complete absence of sickling. Another probable case in a Negro is reported by Faber and Roth.⁶³ Two cases occurred in Palestine in Bucharan Jews whose ancestors had lived for perhaps a thousand years on the shores of the Caspian Sea.⁶⁴ Another case is reported from

South Africa in a European of German and French origin⁶⁶

The mild cases of Mediterranean syndrome have no great significance, except that they represent carriers of a trait that is transmitted in a Mendelian-dominant fashion. Two affected carriers may beget children with the fatal Cooley's anemia, the severest form of this disease. Mild and moderately severe cases are often mistaken for iron-deficiency anemia, lead poisoning, spherocytic hemolytic anemia and even polycythemia. No satisfactory therapy has as yet been established.

Sickle-cell disease, which is largely present in people of African stock, may occur in persons of Mediterranean origin. Sickle-cell anemia with ankle ulcers is reported in a white brother and sister⁶⁸. The sickle-cell trait is noted on the average in 7 to 8 per cent of Negroes. In 5500 West Africans, Findlay, Robertson and Zacharias⁶⁷ found an incidence of 12.5 per cent sickling. Of 403 South African Bantus, however, Altmann⁶⁹ observed only 0.25 per cent with sickling. In the United States Army, Henderson and Thornell⁷⁰ reported a 7 per cent incidence of the trait. It is of interest that, under conditions of lowered arterial oxygen tension, none of the patients showed intravascular sickling or increased hemolysis.

Ponder⁷¹ studied the highly interesting question of how and why the red cell sickles under conditions of reduced oxygen tension, and his paper should be read in the original by those who are interested. The pathogenesis of the development of thrombotic manifestations in sickle-cell anemia is discussed by Murphy and Shapiro⁷². The red cells, under conditions of anoxemia, become rigid, producing mechanical impaction and eventually resulting in slowing of blood flow and thrombosis. The cardiovascular lesions of sickle-cell disease are described by Wintrobe⁷³. Two cases — one of them fatal — of sickle-cell anemia complicated by pregnancy are reported by Noyes⁷⁴ and by Zimring⁷⁵. In the latter case, there was acute illness, pallor and jaundice during labor.

Two new familial hemolytic syndromes have been described in the past year. Rundles and Falle⁷⁶ report a hypochromic, microcytic anemia occurring in association with splenomegaly, increased hypotonic resistance of the red cells and failure to respond to splenectomy. Although in many respects the cases resemble those with Mediterranean anemia, no evidence of Mediterranean ancestry was present. Stransky and Regala⁷⁷ describe 4 cases of hemolytic anemia in 5 Filipino siblings. There was no spherocytosis or leptocytosis, but many nucleated red cells were present. Splenectomy was without effect in 3 cases.

Acquired types. Ross and Paegel⁸ present the case of a four-year-old child who developed an extremely severe acute hemolytic anemia with hemoglobinuria after the administration of a small

amount of sulfadiazine. Hypersensitivity to this drug had probably occurred as the result of two previous administrations. Improvement did not occur until a vein was cannulated and large amounts of blood (1100 cc.) given over a period of eight hours. Cockett⁷⁸ describes the case of a young man who received benzyl-sulfanilamide as a prophylaxis for minor second-degree burns of the legs. Three days later, after 17 gm had been given, weakness, loin pains, hematuria and severe hemolytic anemia developed. Recovery ensued after the administration of two transfusions of blood. Young, Valentine and Howland⁷⁹ report the first case of acute hemolysis following the injection of neoarsphenamine. A previous injection of the drug had caused nausea and vomiting. Five minutes after the second injection the patient developed severe symptoms and died within twenty-four hours. Autopsy showed hemoglobinuria, icterus, spherocytosis and normoblastosis.

Jope⁸⁰ studied the disappearance of sulfmethemoglobin in 7 cyanotic trinitrothrene workers who had developed sulfhemoglobinemia. The abnormal hemoglobin compound was retained within the affected red cell until its destruction, which occurred on the average in one hundred and sixteen days. This period may be considered the life span of the red cell containing sulfhemoglobin.

The development of isoantibodies (hemolysins or agglutinins) within the body may result in auto-hemolysis and thus in hemolytic anemia. Finland et al.⁸¹ found hemolytic anemia in 11 of 200 cases of primary atypical pneumonia. This usually occurred when the maximal titers of cold hemagglutinin were present and was apparently independent of sulfonamide therapy. With marked cold auto-agglutination, there was usually a wide thermal range, so that hemolysis could occur within the circulation as the result of agglutination, which results in increased mechanical fragility. A more general article on the clinical significance of cold hemagglutinins is that of Young⁸². Lubinski and Goldbloom⁸³ report a fatal case of hemolytic anemia in which the cold hemagglutinin had a wide thermal amplitude and was active to some extent at incubator temperature. Boorman and his associates⁸⁴ consider some of the mechanisms by which cold hemagglutinins may become activated to produce hemolysis in the circulation even at 37°C. Cases showing abnormal isoantibodies, either agglutinins or hemolysins, require special consideration when transfusions are contemplated. As stated above antibodies are adsorbed to the red cells in some cases and are not found in the serum. Boorman, Dodd and Loutit⁸⁵ demonstrated adsorbed agglutinin in a series of cases of idiopathic acquired hemolytic anemia by testing the red cells with antihuman globulin rabbit serum. Adsorbed antibody was not demonstrated in familial spherocytosis.

Transfusions and splenectomy remain the chief therapeutic agents in hemolytic anemia. Transfusions alone are rarely effective except in cases due to chemical poisoning and in those due to parasites (malaria and Oroya fever). Splenectomy must be resorted to in many cases, particularly when transfusions have been ineffectual. An excellent prognosis can be promised in familial spherocytosis, but in the acquired hemolytic cases, the outlook is not entirely certain. About 7 of 10 patients do well after splenectomy, but the others are either partially or only slightly benefited, if at all. Attempts to diminish red-cell destruction by a diet low in fat have proved ineffective (Evans⁸⁶). Rare patients with refractory hemolytic anemia have recovered after the removal of an ovarian tumor (Singer and Dameshek⁸⁷ and Jones and Tillman⁸⁸). Penicillin therapy was used with a favorable effect by Merino⁸⁹ in a case of human bartonellosis.

Anemia of Infection

Infection causes disturbances in red-cell development in the bone marrow. Such cases have been studied extensively in Wintrobe's laboratory and reported on in a series of articles by Cartwright and his collaborators.⁹⁰ It was found that a reduction in serum iron, an increase in serum copper, an increase in erythrocyte protoporphyrin and an increase in coproporphyrin output in the urine were present. The serum bilirubin and urobilinogen excretion were normal and thus indicated that hemolysis was not a factor. The red cells were normocytic and normochromic. The anemia failed to respond to iron (oral or intravenous), copper, components of the vitamin B complex, ascorbic acid, Amigen, globin, cystin, methionine or crude liver therapy. Indications of an altered iron metabolism were present, the iron being diverted from the marrow to the tissues and thus being made unavailable for hemoglobin synthesis.

(To be concluded)

NEW HAMPSHIRE MEDICAL SOCIETY

PROCEEDINGS OF THE ONE HUNDRED AND FIFTY-SIXTH
ANNIVERSARY

House of Delegates, June 18, 19 and 20, 1947

THE House of Delegates convened at the Wentworth Hotel, Newcastle, on June 18, 1947, at 7 30 p m, with Speaker Leslie K Sycamore presiding

The following members answered the roll call

The President, *ex-officio*
The Vice-President, *ex-officio*
The Secretary-Treasurer, *ex-officio*
Samuel Feiner, Ashland
Nathan Brody, Laconia
W J Paul Dye, Wolfeboro
Francis J C Dube, Center Ossipee
Albert C Johnston, Keene
James N Ballou, Keene
Marjorie B Parsons, Colebrook
Joseph E LaRochelle, Gorham (alternate for Francis M Appleton)
Israel A Dinerman, Canaan
Leslie K Sycamore, Hanover
Leslie E McKinlay, North Haverhill
Clarence E Dunbar, Manchester
Daniel J Sullivan, Nashua
Samuel Fraser, New Boston
Loren F Richards, Nashua
Robert R Rix, Manchester
Philip M L Forsberg, Concord
Andrew L MacMillan, Concord
Francis Brown, Henniker
John W Blaisdell, Epping
Donald W Leonard, Exeter
Fred Fernald, Nottingham
Raymond R Perreault, Rochester
Daniel F McCooey, Dover
Donald C Moriarty, Newport
B Read Lewin, Claremont
George C Wilkins, Manchester
Samuel T Ladd, Portsmouth
Deering G Smith, Nashua

The Speaker declared a quorum present, and appointed the Credentials Committee as follows Drs Johnston, Moriarty and Dube

On motion duly made and seconded, it was voted to omit the reading of the previous minutes, because of the publication of the proceedings

On motion duly made and seconded, it was voted to dispense with the reading of the reports of the councilors, since they will be published in the *Transactions*

To the Committee on Officers' Reports, the Speaker appointed Andrew L MacMillan, of Concord (chairman), and Loren F Richards, of Nashua, and Donald W Leonard, of Exeter To the Committee on Memorials, he appointed Raymond R Perreault, of Rochester, Clarence E Dunbar, of Manchester, and B Read Lewin, of Claremont To the Committee on Nominations, he appointed W J Paul Dye, of Wolfeboro (chairman), Samuel Feiner, of Ashland, Joseph E LaRochelle and Robert R Rix, of Manchester, and Israel A Dinerman, of Canaan

The Secretary-Treasurer, Dr Carleton R Metcalf, presented his report, as follows

The total membership on December 31, 1945, was 528, that on December 31, 1946, was as follows

PAID	
Belknap County	32
Carroll County	16
Cheshire County	33
Coos County	33
Grafton County	69
Hillsborough County	159
Merrimaek County	77
Rockingham County	55
Strafford County	39
Sullivan County	18
State members	3
	— 534
UNPAID	
Life members	18
Honorary members	5
	— 23
	557

FINANCIAL STATEMENT

RECEIPTS	
January 1, 1946 — balance forward	\$107 24
Belknap County	168 00
Carroll County	90 00
Cheshire County	256 00
Coos County	162 00
Grafton County	352 00
Hillsborough County	852 00
Merrimaek County	442 00
Rockingham County	318 00
Sullivan County	118 00
Strafford County	217 00
Cash received at annual meeting	73 00
Checks received at annual meeting	14 00
Members not in county society	18 00
Donations to National Physicians Committee	235 00
(Strafford County, \$34 Belknap County, \$28 Hillsborough County, \$123, Merrimaek County, \$50 00)	80 00
Benevolence Fund	
(Rockingham County Auxiliary, \$40 Strafford County Auxiliary 1945-46 \$20 Merrimaek County Auxiliary, \$20)	500 00
General Fund — Trustees	85 03
Receipts, 1945 annual meeting	
	\$4087 32

EXPENDITURES	
<i>New England Journal of Medicine</i>	\$515 49
Journals	3 10
Tabular material	500 00
Carleton R Metcalf (salary)	164 71
Printing	56 00
Envelopes and stamps	55 24
Half-tone cuts	155 50
Clerical work	33 99
Telephone and telegraph calls	100 00
Retaining fee	85 01
Guest speakers (fees)	60 00
Cancer Committee	80 00
Dues collected at annual meeting	
Benevolence Fund	40 00
Rockingham County	20 00
Strafford County	20 00
Merrimaek County	
National Physicians Committee (donations)	34 00
Strafford County	28 00
Belknap County	123 00
Hillsborough County	50 00
Merrimaek County	301 19
Madeline A May (stenographer at annual meeting)	162 45
Committee lunches	200 00
New England Medical Council	
Deering G Smith (expenses as delegate to American Medical Association, 1945-46)	691 89
Deering G Smith, Committee in Medical Preparedness	152 93
Auditor, trustees books	10 00
Refund on dues	12 00
Service charges at bank	2 39
	\$3657 22
	430 10
	\$4087 32
Balance January 1 1947	

Although no money was added to the Benevolence Fund from the annual dues during 1946 donations totaling \$80 were received from the auxiliaries of Rockingham County Strafford County and Merrimack County.

In accordance with instructions from the House of Delegates \$60 was given to the Cancer Committee. The number of members on this committee was increased to five.

The Committee on Mental Hygiene was asked to formulate a definite program for outpatient psychiatric care and to report at this meeting.

A year ago a National Emergency Committee was formed consisting of five men who served in the recent war. This committee was asked to consider the service of doctors in the war with the thought that in a future emergency a more efficient plan for medical care could be invoked.

The New Hampshire Board of Health has asked us to form a Committee on Industrial Health and the Committee on Rural Medical Service of the American Medical Association has asked us to form a Committee on Rural Medical Service. Both suggestions have been referred to the speaker of the House of Delegates.

The sum of \$100 was provided for our share in the Council of the New England State Medical Societies. The several meetings of this council were beneficial to New Hampshire, and it is recommended that \$100 be donated to the Council so that we may maintain our membership.

All members of the Society were notified that they could have all issues of the *New England Journal of Medicine* by sending \$1.50 a year directly to the *Journal* and all county societies were notified of the amendment to the By laws that changed the phrase "affiliate member" to "life member".

The Board of Health was informed that in the opinion of the House of Delegates health conditions in restaurants and hotels are lax and should be corrected. This alleged laxity is apparently due to an appropriation from the General Court that does not permit the employment of sufficient inspectors.

The New Hampshire Hospital Association was advised that, in the opinion of the House of Delegates routine chest x-ray examination of patients entering New Hampshire hospitals was a worthy procedure.

The New Hampshire Board of Welfare was requested to send a copy of the present fee table to every member of the Society and was informed that the fee allowances of the Blue Shield would be appropriate for indigent patients who are under the supervision of the Welfare Department.

The annual dues of the Society were raised to \$10.00.

A special meeting of the House of Delegates was held last October at the Snow Shoe Club in Concord to consider the hometown care of veterans with service-connected disabilities. This meeting was attended by a representative of the Veterans Administration from Boston. Dr. Cooper as well as by Dr. Drury, of the Manchester office. The decision was left in the hands of a special committee, with power to act. This special committee had several meetings, drew up an agreement and prepared a fee table for the care of veterans. The agreement has been accepted by the Veterans Administration. The fee table was rejected in part, by the Administration on the ground that some of the fees were larger than those charged other patients for similar services in New Hampshire communities. The Veterans' Administration countered with a fee table that represented the maximum amounts that the Government was willing to pay. Copies of this fee table and of the agreement were sent to each county society with the request that it consider the matter and instruct its delegates in the proper action to be taken at this meeting.

The Taft Bill (S. 545) will probably have hearings in the Senate soon, and according to the newspapers a revised version of the Wagner-Murray-Dingell Bill is also to be presented.

The most important legislation that came before the General Court this year was the hearing on the elimination of Bangs disease in cattle. The Society was represented by the Committee on Public Relations. Dr. Blood spoke in favor of a continuation of the program and the Secretary gave a vivid description of undulant fever with which he was afflicted in 1941.

Our attorney Mr. Sulloway was given his usual retaining fee of \$100. It should be remembered that any member

of the Society is privileged to confer, without expense with Mr. Sulloway on any legal difficulty pertaining to the practice of medicine.

According to the by laws of the American Medical Association the delegate from this state, as well as the alternate delegate, should be elected for two years rather than for one year. It should also be noted that both the delegate and the alternate delegate must have been fellows of the American Medical Association for a period of two years before they are elected.

A return postal card was sent to all members during the course of the year asking them to signify if they would like to serve on one of the committees of the Society. The names of those who wish to serve on a committee have been given to the Committee on Nominations.

A second postal card was sent soliciting volunteers for a speakers' bureau. A questionnaire was sent to all members requesting suggestions to make the work of the Society more interesting and more beneficial.

The Missouri State Medical Association sponsored a contest last year among school children who were asked to write a brief essay on the subject, "What Can Our Community Do to Improve Its Health?" Suitable prizes were awarded. It might be worth while to have such a contest in New Hampshire next fall. We might find some "sore spots" that could be corrected in a constructive way. If such a contest meets with your approval, I suggest the expenditure of \$200 to \$300 in prizes.

For the present, it seems that we must hold our annual meeting at some summer hotel in June. Now that we have returned to a two-day meeting it may be considered unwise to hold a meeting in Manchester because it is practically impossible in that city to get adequate hotel accommodations.

On motion duly made and seconded, it was voted that the report of the Secretary-Treasurer be referred to the Committee on Officers' Reports.

Dr. Macmillan, chairman of the Committee on Officers' Reports, then stated that the Committee had approved the Secretary's report.

The speaker then suggested that Dr. Metcalf say a little more regarding the question of sponsoring a contest among school children on community health.

Dr. Metcalf replied that the contest in Missouri apparently received a considerable response from the school children, that it gave the children and the people of Missouri the idea that physicians were trying to do something constructive for the betterment of health in the different communities and that, in the event that they picked up what he called a "sore spot," an attempt was made to correct that condition. The question was whether it would be worth while to try it in New Hampshire this fall.

Dr. Macmillan stated that the Committee on Officers' Reports had read Dr. Metcalf's report and approved all his suggestions.

Dr. Dye inquired whether funds were available for such a purpose.

The Secretary replied in the affirmative.

Dr. Dye moved that the Society sponsor such a contest, instructing Dr. Metcalf to proceed with it, and that the maximum expenditure be \$300.

This motion was duly seconded and carried.

Dr. Dye moved that the appropriation of \$100 for the expenses of the New England Medical Council be made.

The speaker asked if all the members knew what the New England Council was. He defined it as an organization of delegates from the six New England state societies to discuss the questions that concern the general region of New England. He said that it had no particular power of action but had power of recommendation to the societies, adding that it had conducted general discussions for the memberships of the societies, besides its own discussions, concerning the state of medicine in the New England area.

The President stated that he had attended all the meetings of the Council, which had been important in bringing the viewpoints of the different New England states together. He believed that the medical societies of the six New England states are today much more in accord than they have ever been before, because of the Council.

The Speaker then requested all those in favor of appropriating \$100 for the expenses of the New England Medical Council to manifest assent by saying "aye."

There was a chorus of "ayes," and the motion was carried.

The report of the Committee on the Control of Cancer was then presented by the chairman, Dr. George C. Wilkins.

As usual during the past year your committee sent to every member of the society three one-page letters on important subjects pertaining to cancer diagnosis or treatment. One on cancer of the urinary tract mentioned the two most important symptoms, hematuria and a mass in the flank. Any patient presenting either of these symptoms should be cystoscoped without delay, that an early diagnosis may be made. Cancer of the digestive tract was too large a subject to be treated in one letter, but several important points were emphasized that should lead to earlier diagnosis, such as early x-ray examinations in patients with indefinite but persistent digestive disturbances and repeat x-ray examinations when the diagnosis has been indefinite. Every tumor of the digestive tract should be considered a carcinoma until proved otherwise. More careful histories and more thorough examinations will reveal carcinoma of the colon earlier. This type of carcinoma is appearing more frequently in our cancer clinics and hospitals. Our last letter contained many unrelated hints in short sentences that might refresh the memories of physicians in the methods of making correct diagnoses of cancer and in advising adequate treatment.

The New Hampshire Medical Society was the first to send cancer information of this type to its members. Now many states are doing it, some by means of comparatively voluminous pamphlets and bulletins, but your committee still prefers short, readable articles, which we hope will stimulate interest. Complete information on any phase of cancer is available in medical magazines and in books.

On May 6 the second annual Cancer Instruction Day was held in Manchester. There were eleven speakers on different phases of cancer. All talks were short and concise. A luncheon was served at noon, and the members of the Society attending the meeting are indebted to the New Hampshire Field Army of the American Cancer Society for bearing all the expenses of the meeting as part of their educational campaign. Although ninety members had indicated their intention of attending this meeting, we were again disappointed at the small number of general practitioners attending.

The Field Army has also continued its generous offer of financial assistance to any physician connected with any of the state cancer clinics to take refresher courses at a cancer

center. Two physicians have taken advantage of this offer during the past year.

The lay and high-school educational projects of the Field Army have been continuously functioning, but there are still high schools that have not accepted the ideas or the pamphlets furnished by the Field Army.

The functions of the fourteen cancer clinics of the New Hampshire Cancer Commission have continued as usual. During the year ending July 1, 1946, the smallest number of new cases for several years was recorded. The number always fluctuates with economic conditions, and during the past six months more patients have appeared at the clinics and there have been more applications for financial assistance. Since 1931, when the Commission was established, these changes have been an early and significant barometer of economic changes.

The need for continued intensive education among the laity in the early signs of cancer is being constantly demonstrated by the appearance of patients with advanced cancer in doctor's offices, hospitals and clinics. We must also recognize and admit that there is a continued need for education in early recognition of cancer among the members of the medical profession. This is our problem, and we should do all in our power to remedy this situation.

Your committee expended \$55.56 of the \$60.00 appropriation and requests the sum of \$60.00 for next year's expenses.

Geo C. Wilkins, Chairman

Ralph E. Miller

Walter H. Lacey

Albert Oppenheimer

George F. Dwinell

Dr. Macmillan stated that the Committee on Officers' Reports had approved the report of the Committee on the Control of Cancer.

Dr. Dye moved that the sum of \$60.00 be appropriated for expenses of the Committee on Control of Cancer. This motion was duly seconded and carried.

The report of the Council of the New England Medical Societies was then presented by Dr. Ralph W. Tuttle.

The Council of the New England State Medical Societies has had four meetings within the past year. The first meeting was held in Concord at the Snow Shoe Club on June 9, 1946. Aside from the delegates of the different State Societies there were the following guests: Dr. Robert O. Blood, Mr. James M. Langley, Mr. Frank J. Sulloway, Mr. George M. Putnam, Mr. Charles Gannon, Mr. Arthur J. Connors, of the American Federation of Labor, and Mr. Newell, member of the staff of the Concord Monitor.

Dr. Blood, chairman of the Committee on Maternal and Infant Care, gave an interesting account of the work of the committee in its educational program aimed at the reduction of maternal and infant deaths in the State.

Mr. James M. Langley, chairman of the State Hospital Study Commission, discussed the Hill-Burton Act.

Mr. Frank J. Sulloway, attorney for the Society, discussed methods of handling malpractice suits. He stated that the Society carries on a program of education to teach its members how malpractice suits arise and that three fourths of such suits are due to remarks of medical colleagues who do not know the full facts of the medical case. This education has been effective, as shown by the fact that the members of the Society have had the benefit of five successive reductions in the basic premium rate.

Mr. George Putnam, president of the Farm Bureau of New Hampshire and director of the National Farm Bureau, gave an interesting talk on the medical needs of the rural communities.

A representative of the American Federation of Labor was present at the meeting but did not address the group.

The topics for discussion at the next Council meeting were distributed as follows: public relations (Massachusetts), rural medical care (Vermont and Maine), prepaid insurance (Rhode Island), veterans (Connecticut), medical care (Rhode Island) and licensure (New Hampshire).

The next meeting of the Council was held in Boston at which the subjects stated were taken up. The secretary of the Council Mr Farrell mailed the minutes of the previous meeting to all the members and also had the proceedings mailed and the report on Rural Health Care published in the *Rhode Island Medical Journal*. He sent to each member of the Council reports on the progress of the bills relating to medicine in the United States Senate and House of Representatives.

Dr Tighe, representative from Massachusetts reported on the question of medical public relations. He stated that the Council of the Massachusetts Medical Society had created a new position, Director of Medical Information and Education and that this officer will be charged with organizing two divergent programs a medical education program and one designed to place that society in a more favorable light before the public. Several of the state medical societies have a full time officer to publicize their activities. In some states he is a doctor and in others a layman. It was stressed that public relations is an important part of our endeavor if we wish to maintain the practice of medicine throughout the country in its present form and keep out from under complete governmental control.

Dr Metcalf reported on the seventh annual Congress on Industrial Health sponsored by the American Medical Association, this being the first time the congress has been held outside Chicago. Full co-operation was given by the Council to the American Medical Association and the Massachusetts Medical Society, which sponsored the meeting. The report of the scientific papers presented at the Congress has been published in the *Journal of the American Medical Association*. Programs distributed by the American Medical Association nationally carried us as cosponsor of the Congress.

After a discussion of the Kenny Foundation Campaign, Dr Creighton Barker of Connecticut moved that it be the opinion of the Council of the New England State Medical Societies that the societies in this area should withhold approval of the Sister Kenny Foundation Public Appeal for funds in the opinion that it should secure its funds from already existing organizations to avoid duplication in programs for the control of poliomyelitis. This motion was accepted and unanimously adopted.

Dr Pitts, president of the Rhode Island Medical Society spoke on prepaid insurance and medical-care plans, which were discussed by the delegates from the several states.

Dr Metcalf reported for the New Hampshire Society that the Blue Cross had 173,000 subscribers the Blue Shield Surgical 68,000 and the Blue Shield Medical 15,000. At present the enrollment is much larger. The members from the other states were quite interested in this report. Maine has not done so well as some of the other states because there is more or less difficulty with the osteopaths. Maine is thinking of endorsing a private insurance carrier to write its medical insurance rather than the Blue Cross. The decision has not yet been made. Vermont has adopted the plan of the New Hampshire Physician Service and has formed an alliance with New Hampshire. Connecticut is still working out a program of its own which will probably be somewhat similar to ours.

Dr Cole Gibson, president of the Connecticut Medical Society, reported on the National Physicians Committee meeting in St. Louis. He discussed the work of the committee in Washington and called attention to the recent splendid publication put out by the committee under the title *The Key to Collectionism*.

Dr Miller of Connecticut, inquired if any of the men present had any pronounced opinion concerning the situation whereby trustees of the American Medical Association have also served on the Board of Directors of the National Physicians Committee. There was rather a brief discussion of this point, and Dr Metcalf called for a show of hands as to whether it was believed that there should be separation as regards such participation. The vote showed that nine signified that they believed the trustees of the American Medical Association should not also serve on the Board of Directors of the National Physicians Committee. There were no negative votes, but several members did not vote on the question.

The agenda for the next meeting included hospitals (New Hampshire) group practice (Connecticut), health education (Rhode Island) labor relations (Massachusetts), legislation (Vermont) and medical economics (Maine).

The third meeting of the Council was held in Boston on January 1. As usual there was an excellent attendance. Guests at this meeting were Dr. Frank J. Lawless, Harold Q. Gallupe, John A. Bolster and John S. Wheeler, respective secretaries of the boards of registration in medicine in Vermont, Massachusetts, Rhode Island and New Hampshire and Dr. Leroy E. Parkins, chairman of 1946 Postgraduate Assembly, and Mr. Robert St. B. Boyd executive secretary of the Massachusetts Medical Society.

There was a proposal from the Massachusetts Medical Society that the New England Postgraduate Assembly, hitherto sponsored by the Massachusetts Medical Society with the co-operation of the other New England medical societies be sponsored by the New England societies through the Council of the New England State Medical Societies. After considerable discussion it was decided that the Council was not in a position to commit the different state societies to the sponsorship of the program without having approval from the respective societies. This is a problem that should be taken up by each of the medical societies for a report to the Council next year. The Massachusetts Medical Society will sponsor the New England Postgraduate Assembly this year as they have previously done waiting confirmation by the different state medical societies as to whether they wish to co-operate with the Massachusetts Medical Society in sponsoring meetings in 1948.

Prior to the war the Assembly was held at Sanders Theater in Cambridge. No exhibits were permitted, but a nominal registration charge was made of persons attending the Assembly. The registration in 1941 was 699, and the total income was \$2,828.25. A net profit of \$301.41 was realized.

In 1946 the Assembly was renewed and was held at the Hotel Bradford, Boston. Exhibits were permitted. The total registration of physicians was 488. The income from exhibits was \$3,600, and from registrations and tickets, \$3,202.45. The total income was \$6,802.45 and the total expense was \$5,964.97. The net profit of \$837.48 accrued to the Massachusetts Medical Society.

It is planned to hold the 1947 Assembly at the Copley Plaza Hotel, Boston, on October 29, 30 and 31. The ballroom, foyer, Colonial Room and Sheraton Room are to be used for exhibits and meetings. Possible income from exhibits is expected to be \$4,500. (Forty-five registrations at \$100 each.) Hotel rental charges are expected to be \$1,125. Luncheons for two days and dinner for one evening will be at the regular charge to registrants. The registration fee for 1947 will be \$2.00.

The question arises, Does the New Hampshire Medical Society wish to sponsor the Assembly?

Dr Metcalf reported for the subcommittee of the Council representing the New Hampshire delegation on the subject of hospitals in the post war world read the following summary of a complete report submitted by the committee.

We suggest the following trend in hospitalization in the post war world:

Expansion of the general hospital with increasing acceptance of communicable diseases of certain types of tuberculosis of nervous and mental ailments and perhaps in separate pavilions, of care for patients in the convalescent and chronic stages.

Increasing subsidies from the federal, state or county governments. The Hill-Burton Bill provides a subsidy. For "relief" patients the Government under its different programs pays only about 50 per cent of the actual cost of medical care. It should pay the entire cost for the patient so classified.

Extension of physical and occupational therapy. State licensure for all institutions that care for the sick—supervised we hope by one agency.

Responsible boards of trustees who will co-operate with the medical staff and with a sure fire administrator who has his feet on the ground.

Two groups of nurses, besides the graduates—the first group with better background and a longer train-

ing period, and the other, for the simpler tasks, with briefer training

Higher wages for nurses and for all hospital personnel The American Hospital Association is working on the problem of pensions Social Security does its part, but it should be furthered by a fund contributed by the hospital and the employees themselves

An increase in the number of doctors who have their offices in hospitals and an increase in group practice.

A gradual increase in the cost of hospital care, which will be materially alleviated by insurance plans

Public-health centers in areas of scanty population, rather than an increase of small hospitals

Closer co-ordination among hospitals, perhaps under the sponsorship of hospital councils

In discussion Dr Pitts reported that he had been informed that there had been no applicants for the new nursing class at Rhode Island Hospital that was to start in February, showing that the nursing situation promised to become critical

Dr Rice, of Massachusetts, discussed the program in that state for licensed attendants Dr Gallupe, secretary of the Massachusetts Board of Registration, stated that the board had approved eleven schools for licensed attendants with courses running from one year to eighteen months He expressed the opinion that it was an excellent method to provide nurse auxiliaries He further reported that Boston University was planning to inaugurate a five-year course in its new school program Dr Yeager, of Connecticut, stated that at a recent nurses' meeting in Hartford there had been much discussion of why nurses do not start training because of the conflict between nurses with college education and those with high-school training He also reported that industry had attracted many nurses and nursing personnel

Dr Tighe, of Massachusetts, spoke on labor relations He cited the two questions proposed the advisability of meeting with labor leaders and the discussion of mutual problems regarding health and welfare He recommended that for the time being action on a meeting be postponed He amplified his reason with remarks off the record He observed that it was the general belief of labor that industry should pay the costs of medical care, whereas industry considers the main expense involved in assisting in medical care for employees, other than inpatient plant service, to accept the cost of services involved for payroll deductions and so forth, to enable employees to purchase insurance, both from nonprofit and from casualty carriers Dr Welch remarked that one source of opposition from employers has been the fact that wage increases are known and publicized but that insurance benefits are not given equal publicity, hence, employers are not too favorably inclined to expand or to continue some of their programs now in operation

Dr Pitts spoke on health education He reported that the subcommittee assigned to the topic had decided to concentrate on the matter of statewide health federations or councils under the sponsorship of the medical societies Men from each state reported that there was some health-education plan in each of the different states They believed that this subject should be taken up more fully by the state medical societies

The subject of medical licensure was brought up The secretaries of the boards of registration in medicine in Vermont, Massachusetts, Rhode Island and New Hampshire were present, following a meeting of their own in another room The following report was submitted at this meeting, and as a result of the adoption of these regulations, licensure by endorsement will be possible in all the New England states except Maine, where the statutes prohibit it

The Rhode Island licensing authorities have given careful consideration to the possibility of establishing reciprocal relations with other New England states for the issuance of medical licenses The Rhode Island Medical Board does not consider straight reciprocity advisable or permissible under the present medical act. The board has voted, however, to exempt any licensee from another New England state from the usual written

examination, provided the requirements of the Rhode Island law are fully met by the individual applicant Such candidates will be treated in the same manner as diplomates of the National Board of Medical Examiners After evaluation of their credentials, they will be required only to appear before the Board of Examiners for an oral examination, which is actually more of an interview than an examination

It should be emphasized that the issuance of medical licenses by endorsement after oral examination is discretionary with the board A licentiate who is not in good standing with the licensing authorities of his home state will, of course, not be considered Also, Rhode Island will consider candidates for endorsement from only states that extend the same privilege to physicians registered in Rhode Island

Recently, the Rhode Island Board of Examiners in Medicine held a joint meeting with the Board Examiners in the Basic Sciences, and the latter will issue a certificate of ability in the basic sciences by endorsement after oral examination to candidates who meet the following qualifications

That he has passed in another state an examination in the basic sciences held before a board of examiners in the basic sciences or before a state board authorized to issue licenses to practice the healing art.

That the requirements of that state are not less than those of Rhode Island so far as the basic-science subjects are concerned

That the board of examiners in the basic sciences of such state grant like exemption to persons holding Rhode Island certificates in the basic sciences

The fee for a certificate by endorsement would be the same as that for the regular examination — \$10.00 in the basic sciences and \$20.00 in medicine

The fourth meeting of the Council was held at the Harvard Club of Boston on April 16, 1947, with the usual full attendance Mr John E Farrell, the executive secretary, gave an excellent report of the activities of the year

Dr Metcalf called for discussion on the proposal of the executive secretary in his annual report for regional conferences of committees of the various state medical societies in this area on various problems concerned with medical economics Dr Miller, of Connecticut, suggested that copies of this report be submitted to Dr Lull, secretary of the American Medical Association, with a request that he in turn submit it to the committee planning the Conference for County Medical Society Officers at the time of the American Medical Association meeting in June He expressed the opinion that the idea of regional meetings should be incorporated in the discussion at this particular conference He also stated that it might be advisable to have the various state societies in New England know of the desire of the Council of the New England State Medical Societies to assist them in educating their various committees in mutual problems regarding medical economics This was discussed favorably by several members of the Council

Dr Metcalf summarized the opinion that the executive secretary should notify the secretary of each medical society regarding the desire of the Council to sponsor such conferences, and also to inquire whether the respective committees in the societies wished to participate at a meeting in the fall, possibly on the subject of medical public relations

The executive secretary, in the absence of Dr Rice, read his report regarding financing the Council, as follows

At present there seem to be two ways of raising funds for this Council The first is in the way it has been done by assessing each state society the same amount Naturally, state societies with small memberships believe that they should not pay so much as state societies with larger enrollments The second way would be to assess each state society an amount proportional to its membership roll Again, quite naturally, state societies with large enrollments believe that they are carrying too much of the financial load This method was tried a generation ago by an organization similar to this and came to grief over the issue

There might be a third way. The Council hopes to take over the Postgraduate Assembly, conducted for several years by the Massachusetts Medical Society. Is there not reason to believe that this venture could be so managed as to yield enough profit to enable the Council to undertake further activities?

If this offer seems unwise, the conclusion is that this Council should raise its funds, as heretofore, by equal assessments from each state society.

Drs. Howard, O'Hara and Gibson entered the discussion and expressed the opinion that the Council should not branch out at this time. Therefore Dr. Metcalf moved that the Council continue to finance its program as in the past with each of the state medical societies contributing \$100. Dr. Cole Gibson seconded the motion, which was unanimously adopted. It will be necessary for the House of Delegates to appropriate \$100 for this purpose.

The president stated that a request would be sent to the Secretary of each of the medical societies requesting that official delegates be named at the time of the annual meetings of the various societies. Mr. Farrell called attention to the fact that it has been the policy to invite past delegates to attend all Council meetings and he suggested that some official action should be taken in this matter.

Dr. Gibson moved that all former members of the Council of the New England Medical Societies be officially designated as honorary members and that they be invited to attend the meetings of the Council and, further, that from time to time such honorary members be communitated with to see if they wish to continue on the mailing list of the Council to receive notices and invitations of meetings. The motion was seconded and unanimously adopted.

The nominating committee submitted the following nominations for officers for the ensuing year: for president, Dr. Arthur H. Ruggles, Rhode Island; for vice president, Dr. Stephen A. Cobb of Maine; and executive secretary, Mr. John E. Farrell, of Rhode Island. Dr. Pitts moved that the nominations for officers be closed; the motion was seconded and approved. He then moved that the secretary be empowered to cast one vote for the slate as nominated. The motion was seconded and unanimously adopted.

Dr. Norman H. Gardoer, of Connecticut, a member of the National Committee on Rural Medical Service of the American Medical Association, addressed the Council on the matter of planning for rural medical services by state medical societies. There was a general discussion of the subject. Dr. Gardoer reported that the Connecticut State Medical Society planned to conduct a conference on rural health at Connecticut University at Storrs on July 16, and he requested that the Committee on Rural Health in each state society attend this conference. Mr. Ambrose B. Kelley, a former member of the Committee on Social Insurance of the National Association of Mutual Casualty Companies and a guest of the Council, commented on the procedure regarding the writing of insurance by private companies for persons living in rural areas, and stated that the private insurance companies cannot write the contracts on an individual basis at a low cost. He observed that the Grange in many communities works closely with the Farm Bureau and has served as an excellent outlet for the distribution of insurance. Dr. Metcalf reported in detail on the situation in New Hampshire, and Dr. Gardner closed the discussion by urging that each state have a rural-health committee to strengthen the work of the national committee so that it will be in a position to report that there was an active committee in every state concerned with the problem.

Dr. Reginald F. DeWitt, of Plymouth New Hampshire spoke on the subject of group practice in a small community. An interesting discussion followed.

Mr. Kelley spoke on the relation between the medical profession and the insurance companies and the problem of socialized medicine. In discussing national legislation he pointed out that the proponents of the Wagner-Murray-Dingell Bill had proved themselves better salesmen than the physicians whose case may have been better and whose logic was probably irrefutable, but whose dramatization of the problem fell far short of that of the social plan-

ners who appealed to the emotional phases of the entire issue.

Dr. Macmillan then stated that the Committee on Officers' Reports approved the report of the Committee to the Council of the New England Medical Societies and suggested that it be accepted.

The President observed that if the House of Delegates wished to approve the recommendation that the Council of the New England State Medical Societies sponsor the Postgraduate Assembly, it could report to the Council that it had done so but that each of the other states would have to act similarly before the Council could sponsor the assembly. He added that sponsorship would not entail any expense on the Society, unless for some reason the assembly which had heretofore been profitable, should fall far short. The Assembly would be better attended, if each state had its own sponsorship, instead of sole sponsorship by the Massachusetts Medical Society, and this course would probably make the Assembly much larger than it is at the present time.

Dr. Sullivan stated that sponsorship of the assembly by the New England Council would involve six hundred members and, if it were a success, even more. He asked for suggestions concerning where meetings could be held.

The Speaker observed that the assembly need not be held in New Hampshire and that some central city, such as Boston or Worcester, would be better able to accommodate the members.

A member inquired if the profits, if any, would accrue to the Council or to the Massachusetts Medical Society.

The President replied that profits would definitely accrue to the Council and that if the profits were large enough, the \$100 supplied every year would no longer be necessary. He added that if the Council could become a concrete entity, which, in itself, might have a backlog after a few years, it could expand and do far more toward the promulgation of the good of the practice of medicine in all New England. He moved that the House of Delegates be empowered to vote in favor of the sponsorship of the new assembly. This motion was duly seconded.

The Secretary stated that the Assembly had always been held in Boston, with usually three or four hundred physicians from Massachusetts and a scattering from the other states. Last year, he added, there were 23 men from New Hampshire. He therefore believed that there would probably be a large attendance from Massachusetts, Connecticut and Rhode Island and that the meetings should be held in Massachusetts, perhaps in Boston. Consequently, the Massachusetts Medical Society would have to continue active support.

He then raised the question what would happen under the proposed sponsorship, if there was a deficit in any year. The assumption was, on the part

of the men from Massachusetts, that that deficit would be taken from the several New England medical societies, pro rata. In other words, the Massachusetts Medical Society would pay a larger proportion of the deficit than the New Hampshire Medical Society.

He assumed that the Massachusetts Medical Society would ordinarily run the meetings and that there would be a delegation from New Hampshire, which would be on the executive or sponsoring committee and would try to interest the men in New Hampshire in this meeting.

The Speaker then requested all those in favor of the motion to manifest assent by saying "Aye."

There was a chorus of "ayes," and the motion was carried.

The report of the Committee on Maternity and Infancy was then read, as follows:

This is the thirteenth year in which the New Hampshire Medical Society, through the Committee on Maternity and Infancy, has conducted a study of maternal and infant deaths during the previous calendar year. The study is conducted with the co-operation of the New Hampshire Department of Health, which gives the services of personnel in the divisions of Maternal and Child Health and Vital Statistics. All data are gathered by the Division of Maternal and Child Health, acting as agent for the Committee on Maternity and Infancy. Death reports are received in the Division of Vital Statistics and, after checking and coding of the causes recorded on the death certificates, are transmitted to the Division of Maternal and Child Health for follow-up information on each case. The members of the committee, it should be pointed out, do not know the identity of the patient, physician, hospital or community where the patient was delivered. It is important to point out that a study of this kind is made possible only through the co-operation of the reporting physicians, since decisions made are based entirely on the information at hand. The committee has endeavored, as in all past studies, to analyze openmindedly all information in each case that can be obtained and has attempted to appraise the data so far as possible, having the advantage of reviewing the events in retrospect and not admittedly being in the position of the physician in charge of the case, who must make his decisions on the spot. It is with this thought in mind that the committee wishes physicians to read the recommendations and suggestions made, with the hope that such comments as are made may be of value in the conduct of future cases presenting similar problems.

The committee wishes to emphasize the fact that this report and study are for the purpose of making available to the practicing physician information on maternal deaths and their causes. It is therefore essential that physicians respond as promptly as possible, giving as full information as they can on each case reported by them, this year, only two physicians failed to respond to the committee's request.

As a matter of record, the committee believes that the method of conducting this study should be described. After the data have been gathered, either through personal contact of a member of the Department of Health or by letter, the information is presented to the committee without identifying information. Each member of the committee has a copy of the report to study. A discussion of the details concerned with each case ensues. Then the decision of the committee is recorded. The committee classifies the causes of death in accordance with the facts. This classification may differ from that of the Division of Vital Statistics, according to the *International List of Causes of Death*. The only information that the Division has, of course, is the diagnosis of the physician recorded on the death certificate. The discrepancies in classification, therefore, are based on the fact that as the com-

mittee receives additional information the cause of death becomes more apparent. This year, for instance, there were 4 deaths reported as maternal deaths that the committee considered to be due to other causes, such as surgical shock and, in 2 cases, anesthesia. One death was believed to be due to self-inflicted poison.

Over the years during which these studies have been performed, there has been a real decrease in the maternal death rate. The committee would like to suppose that its efforts in indicating poor obstetric procedures to individual physicians is—in part, at least—responsible.

TABLE 1 Number of Maternal Deaths by Cause

for this fact. Tables 1-5 present the causes of death and other data on maternal deaths since 1933.

The committee further classifies the cases into four groups, as follows:

Group I Cases in which the patient was at fault because of refusal of prenatal care, neglect, self-induced abortion and so forth (1 case).

Group II Those in which the obstetric treatment was inadequate (2 cases).

Group III Those in which death was apparently unavoidable (7 cases).

Group IV Cases in which data were insufficient, and in which the cause of death was therefore undetermined (6 cases).

(It has been found that in some cases inadequate information frequently signified inadequate treatment.)

After the committee has made a decision in each case, including suggestions for conduct in the individual case,

a letter containing this information is written to the reporting physician. It is hoped that this procedure will aid physicians in selecting the proper treatment for their patients. The committee fully realizes how much easier

it is to decide the course of a case at a round table discussion than at the bedside at the moment when treatment is necessary.

In the study of maternal mortality by years it is interesting to note that the highest rate occurred in 1933, at about the time that the studies began. There has been a slowly receding rate through 1942, but in 1943 there was a rise in the rate, which remained stationary through 1944 and started to drop again in 1945. The rate in 1945 was 18 per thousand live births. The number of maternal deaths was 16 with a slight decrease in the number of births as compared with the previous year. There were 8551 births in 1945. In 1946 the year of this study, 16 maternal deaths were reported and the birth rate reached an all-time high. The number of births reported was 11,489. This gives a maternal death rate of 14.

The committee is not discussing infant deaths or stillbirths in this report but Table 3 presents the causes of death among infants under one year of age, and Table 4 a list of the chief causes of death in stillbirths. The committee would like to call attention to the number of infant deaths. It is believed that the accepted definition for a stillbirth should be restated in this report: the status-legal definition adopted for use in the United States and the one accepted by the Children's Bureau of the American Public Health Association: the Bureau of the Census and the one now in use in New Hampshire is as follows: "A fetus showing no evidence of life after complete birth (no action of heart, breathing or movement of voluntary muscle). If the twentieth week of gestation has been reached should be registered as a stillbirth."

MATERNAL DEATHS

During 1946 a total of 16 maternal deaths were reported. The number of births in the state was 11,489 giving the official rate on the basis of 16 deaths in terms of 1000 live births of 14. It is gratifying to the committee that the majority of the deaths were unavoidable because of insufficient data, however or no data at all the committee has had to classify more maternal deaths as "undetermined" than in any previous years.

In the group of deaths for which responsibility was undetermined, it was interesting that there were 2 cases of inversion of the uterus. From what could be ascertained both patients died of post partum hemorrhage after the uterus had become inverted during the third stage of labor. This condition is admittedly a startling and sometimes dramatic situation. The committee wishes to suggest that no placenta should ever be delivered by a Credé maneuver unless one hand is between the fundus and the symphysis. If this procedure is observed inversion of the uterus cannot occur. (By a Credé procedure is meant the squeezing of the uterus by the exertion of anteroposterior pressure and avoidance of downward pressure. Delivery of the placenta should not be attempted until it is obviously detached.) It is recognized by the committee that spontaneous inversions occur but also that every attempt should be made to avoid such a situation by warning against a forceful Credé and taking the precaution described above. In 1 case the committee believed that, although the physician described replacing the uterus, despite which bleeding persisted the uterus may have been pushed back into the vagina without completely reducing the inversion.

The causes of other undetermined deaths were given as follows: chronic nephritis with premature delivery of six month, stillborn twins and uremia with a stillbirth after which multiple infarctions were found in the liver and kidney with a complicating thrombophlebitis.

The group that the committee classified as unavoidable posed some interesting problems. These cases fell into two groups: death occurring from intruterine or post-partum hemorrhage and toxemia of pregnancy. One of these cases was a woman of twenty-eight years of age who, during her fourth pregnancy developed a sudden attack of acute lower abdominal pain that came and went at varying intervals. Examination during these attacks revealed nothing unusual and although she had been admitted to a hospital for study she was discharged twice with no findings. There was no external bleeding and finally the patient in her last attack went into shock and expired. Autopsy revealed torsion of a five month pregnant uterus filled with blood. The interesting fact

in this case was that there was a history of a ventral fixation of the uterus several years previously the patient, however had gone through a normal pregnancy and delivery following that operation and it is difficult to explain why torsion did not occur at that time but was the final cause of death in the later pregnancy. The committee believed that a ventral fixation, similar to the so-called "Kelley ventral fixation," should not be performed in the child-bearing age.

Again, in 1946, the leading cause of death in the cases studied was toxemia of pregnancy. In several cases it was noted that the treatment given to eclamptic patients

was sodium chloride or mention of glucose and hyper-tonic salts was made. The committee wishes to stress the fact that eclamptic patients should not be given sodium chloride and that early treatment of toxemia is imperative. One case of toxemia was charged to the patient, who did not appear for prenatal care but presented herself in labor with a high blood pressure, a +++ test for albumin in the urine and definite signs of toxemia. Even though the physician instituted immediate treatment with magnesium sulfate and hypertonic glucose and delivery was spontaneous the patient died fourteen hours later. The committee repeats its recommendation concerning the treatment of toxemia—namely that as soon as the condition has been discovered the patient be given magnesium sulfate that early induction of labor be performed in accordance with the degree of prematurity that glucose be given intravenously with magnesium sulfate in severe cases and that oxygen and digitalization be employed in convulsive toxemias. It was of interest that the cases of toxemia reported in this series showed evidence of definite chronic nephritis or previous kidney damage. The committee doubted whether 1 case so reported was a

true toxemia, since the blood pressure was low and the signs not too clear cut. The committee believes that if permission for autopsy could be obtained in more of these cases, a definite diagnosis could be made, the fact that more autopsies are not performed is deplored.

The most striking fact concerning the type of cases studied this year was the lack of puerperal infections. There was only 1 case in which the mention of an infection was made. In this difficult case a young primipara, who had had a perfectly normal prenatal course and who had received excellent prenatal care, had a short tempestuous labor of three and a quarter hours and delivered a stillborn child. It was believed that these events indicated a premature separation of the placenta. The course that followed was tragically futile in that, despite every effort on the part of the physician and the consultants, the patient continued to bleed profusely and developed a post-partum infection. Every treatment, including the use

of penicillin, was given, and heroic efforts were made to control the infection and the bleeding. It was known that there was a lower uterine-segment laceration, as well as infection, and as a last resort the physicians decided on a hysterectomy, taking the chance of a fatal infection but realizing that anything less would probably result in a fatal hemorrhage. The patient did remarkably well after operation, but, despite transfusions and intensive treatment for the infection, she could not handle the infection enough to prevent the sloughing of the cervix, with hemorrhage, that finally caused her death about three weeks after operation. This case, because of its severity and possibly because of an individual resistance to the use of modern weapons against infection, is the exception rather than the rule. With the use of penicillin and the sulfonamides, the number of deaths due to infection has definitely decreased.

Another group of cases that deserve comment are those due to anesthesia. The importance of anesthesia during labor and delivery is emphasized, it is essential that a qualified anesthetist administer the anesthetic. The committee believes that a spinal or caudal anesthetic, when chosen, should be given only by qualified physicians trained in such techniques.

The following opinion of the New England Society of Anesthesiology concerning the question of anesthesia may be of value to physicians in the consideration of the importance of anesthesia.

It is the opinion of the New England Society of Anesthesiology that the administration of anesthesia is a form of medical practice.

A thorough grounding in all stages of medicine is essential for the selection of the proper agent and method and for its safe administration.

There are so many dangers inherent in all types of anesthesia that the success and safety of all the various methods is directly proportional to the experience and training of the person responsible. These dangers are so numerous and serious accidents are so imminent that it is imperative for a physician to be in constant attendance throughout the entire administration.

Serious or potentially fatal complications are especially prone to occur during the course of intravenous anesthesia, spinal anesthesia and caudal analgesia. Since these accidents are usually preventable it is our opinion that a physician conversant with these dangers should be in constant attendance.

COMMENTS AND RECOMMENDATIONS

The committee wishes to state that adequate study and recommendations are possible only if the physicians in New Hampshire co-operate in the task of promptly presenting full data. This year, the study was made exceedingly difficult because of lack of response to the requests concerning the cases of maternal deaths reported. The data were either incomplete or lacking. Two physicians failed to respond at all. On the other hand, the majority of physicians who returned information did so completely and promptly.

It is recommended that intensive efforts to obtain permission for autopsy be made on the part of physicians after maternal deaths. This will usually assure a more accurate diagnosis and will thus avoid some of the discrepancies that occur in the final reporting of maternal deaths. It should eliminate to a large degree the element of guesswork in the final analysis.

The committee wishes to stress the importance of good prenatal care when patients present themselves early in pregnancy. It was noted that in some cases in which the patients were seen by the third month, physicians failed to do regular prenatal examinations. In at least 1 case of toxemia, the patient was allowed to go into convulsions without the institution of treatment. It is well recognized that many patients are careless about reporting to the physician early in pregnancy or are reluctant to admit their situation and to seek medical care. The committee wishes to recommend further that, when a physician is fortunate enough to have a patient seek his advice, he render the best possible prenatal care. The most important initial part of this care should consist of a complete physical examination, including laboratory tests, and a complete history, so that a thorough appraisal of the patient's past, present and future status can be determined.

The committee wishes to reiterate its recommendation that eclamptic patients be treated by the use of magnesium sulfate in the early stages, early induction with careful planning as to the stage of pregnancy, glucose and magnesium sulfate in severe cases and the use of oxygen and digitalization in convulsive toxemias. The administration of sodium chloride should never be condoned, and the drug should definitely be excluded from the therapy of toxemic patients.

The committee wishes to repeat its opinion concerning the importance of trained anesthetists. The training of physicians in the skill of anesthesia should be encouraged.

The committee wishes to comment on the apparent drop in the number of post-partum infections as a cause of death. It is hoped that with the continued use of penicillin and other modern weapons against infection this cause of death in maternity cases will be eliminated. It is recognized that individual cases present impossible problems owing to individual resistance or drug idiosyncrasies.

The committee wishes to encourage better record keeping on the part of physicians and hospitals. After a lapse of time, the type of record that is carried around in the head becomes of no value and cannot be used as a defense or safeguard for any purpose. Good records are a good investment for both the hospital and the physician.

The committee wishes to thank the physicians and hospitals that responded to their requests for information concerning maternal deaths and for the help they rendered in making this report possible. The committee will be happy to receive any recommendations or suggestions from the physicians throughout the state that may be helpful regarding these annual reports.

The committee wishes to acknowledge with appreciation the co-operation of the State Department of Health, through its divisions of Maternal and Child Health and

Vital Statistics, in furnishing data and personnel in the preparation of this report.

ROBERT O BLOOD *Chairman*
BENJAMIN P BURPEE
JAMES SANDERS

Dr Macmillan moved the acceptance of this report

This motion was duly seconded and was carried. Dr Dube then presented the report of the Committee on Medical Economics, as follows

New Hampshire Physician Service

The past year has been one of rapid expansion and development. The most important step taken has been the extension of the service to Vermont, with the transformation of the Corporation to the New Hampshire-Vermont Physician Service, effective last October. The membership of the Corporation and the Board of Directors and its subcommittees has been expanded to include representation from Vermont. The Vermont Medical Society has been active in enrolling its members, and an enthusiastic response has been made.

Since the program to Vermont is still in its initial stages the figures given below refer almost exclusively to the New Hampshire Physician Service.

Growth in enrollment has continued at a gratifying rate. Of the forty five medical service plans in the United States that are associated with Blue Cross and have a total enrollment of 4,200,000 our own service now stands fourth in size.

There are at present, in round numbers, 110,000 subscribers to the Surgical Division and of these 40,000 are also enrolled under the Medical Division. It is interesting that the latter group, which increased at a much slower rate than the surgical in the first two years, is now expanding at approximately the same rate as the surgical.

Favorable loss ratios in both divisions have made possible an increase in benefits. There has been an upward revision of many items in the surgical schedule, and allowances for medical visits have been increased. The first step in preventive medicine has been taken with provision under the medical contract for allowances for immunization injections for infants under one year of age.

Veterans' Care

A highly significant development in the field of medical economics is the inclusion of the private physician in the program of medical care for veterans. The contribution of medical-school faculties under supervision of the dean's committee has made possible the present high standard of service achieved in Veterans Administration hospitals. A further step in the program is the utilization of the local physician in providing care for service-connected disabilities of the veteran. This arrangement is in effect in several states and is being presented for the consideration of this session of the House of Delegates.

This program is, of course, a form of so-called "government medicine." It is set up, however, in accordance with the principle previously advocated by the committee in discussing the relation of Government to medicine: the participation of the Government is confined to the economic aspects, and the physician is left in control of the professional relations. The committee therefore endorses this program and recommends its adoption by the New Hampshire Medical Society.

Senate Bill 545

Committee hearings are now being held on this bill. Proposed by Senators Taft, Smith, Ball and Doonell it would establish a national health agency under which the various health activities of the federal government would be co-ordinated, would provide for the appropriation of \$200,000,000 annually for assistance to the states affording medical, hospital and dental services for low-income patients, with provision for medical and dental examinations of school children and would authorize specific funds for research in cancer and in dental diseases. A significant item in the bill is the permission specifically granted for utilization of non-profit medical and hospital service plans in providing such care.

Many problems would arise in the administration of such a bill, the most serious one being the method of determining a person's eligibility for assistance. This presumably would have to be handled on the local level, as in relief cases and it would be difficult to avoid the stigma of pauperization.

The committee approves the bill in principle, pending clarification of the details of administration.

L. K. SYCAMORE, *Chairman*
F. J. C. DUBE
R. W. ROBINSON

Dr Johnston stated that he understood that administration of the procedures authorized by S 545 was to be left up to the state and local authorities and moved that the Society determine who would be responsible for administration in the state and appoint a committee to take up this problem.

The motion was not seconded.

Dr Sullivan stated that the bill under discussion was definitely socialistic, like other proposals, although it was couched in such terms that its socialistic tendencies were not quite so obvious as those of others proposed in Washington, adding that certainly, the method was clear if one looked into it deeply enough. Supporters of the bill stated that the administration of its provisions would be on the local basis, but the local administration of such a method would ultimately get back to Washington, the location of the head of the organization. He doubted whether any part of this bill were any better than those of any heretofore proposed.

Dr Dye moved that, since the question of clarification was the only controversial point involved, the report be accepted.

This motion was duly seconded.

Dr Richards believed that in trying to avoid federal interference with medicine, which many people considered inevitable, and at the same time voting to approve the bill under discussion, the Society would be acting in a contradictory manner.

Dr Johnston stated that the bill was being passed quickly and that aid would be given to New Hampshire with the implementation of the bill, which was a grant in aid. He agreed that it constituted inter-

ference in medicine, but the bill assumed that local authorities would determine who is indigent. If the motion of Dr. Dye to accept the bill in principle were carried, a whole year would have passed before action, and this bill, in all probability, would have become law by then, the grant in aid to New Hampshire could not be implemented during that period.

The Speaker replied that the bill, of course, did not require endorsement by the Society.

Dr. Sullivan objected to the fact that the report of the Committee on Medical Economics ostensibly pertained to the Blue Cross and Blue Shield organizations in New Hampshire but also concerned the proposed bill in Congress. In other words, the proposal for approval of the committee's report, which comprised accolade for the Blue Cross and Blue Shield, also involved approbation of a socialistic piece of legislation. He thought that the two subjects should be separately discussed.

Dr. Dye stated that if passage of the bill were inevitable, the action of the House of Delegates would not change matters. Although he was opposed to socialized medicine, he understood that the various officers of the American Medical Association and the president of the National Hospital Association and others believed that this bill did not really infringe on the independent rights of physicians. If some sort of socialized medicine could not be avoided, the bill under discussion contained provisions that everybody wants, moreover, it offered an opportunity for local control of its administration. This particular seemed to be the least of a great many evils.

He therefore believed that the committee's report should be accepted, although he agreed that it should be voted on section by section. No definite federalized control of medicine, with compulsory employment of physicians and compulsory payroll deductions for everybody and a sort of panel system of medicine, like that in England, was envisaged in this bill.

The speaker made a point of order that the question before the House was the Senate Bill. Therefore, the motion would have to relate to the bill, rather than to the whole report.

Dr. Dye agreed with this statement.

Dr. Dimerman requested a recapitulation of the highlights of the bill under discussion.

Dr. Dube then read the portion of the report concerning the bill, adding that in his opinion the proposed legislation contained no more social medicine than was already in effect, in the care of the indigent in the towns, except that in the small towns inadequate care is often given. He compared the situation with that of old-age assistance, which could be regarded as a form of social medicine in that the beneficiaries would not receive the care unless the funds were granted in part by the state, town and federal governments. Before the in-

auguration of old-age assistance many older people went without medical care, because some of the town fathers refused to appropriate enough money to take care of these people adequately. The bill under discussion was apparently a grant-in-aid to take care of such cases as could not be cared for locally.

Dr. Feiner inquired whether anyone at the meeting had any knowledge of the reactions of Massachusetts and Vermont and other states to the bill and whether anyone knew how the National Physicians Committee had reacted to the bill. He added that although he believed that socialized medicine was inevitable, the House of Delegates did not have to approve it.

Secretary Metcalf stated that he did not know about the other New England states but that the Taft Bill had been approved by the National Physicians Committee and also by the American Medical Association. Senator Taft, he pointed out, had walked out on the hearings on the Wagner-Murray-Dingell Bill, which he considered to be socialism, and had promised to put in a bill to take the place of that bill. The result was the bill under discussion, which was proposed with the idea of avoiding the extreme socialism of the Wagner-Murray-Dingell Bill and for providing funds for the care of poor people in the different states, to be administered on a local basis. It was pointed out that the federal government had been giving New Hampshire grants for venereal control, tuberculosis control and other items for many years. The proposed legislation was simply an enlargement of what was already being done, as well as a counterattack, on the Wagner-Murray-Dingell Bill, on the assumption that if a bill of this sort goes through, there will be less likelihood of passage of the other legislation.

Dr. Brody observed that the severest critics of the American system of medicine were those who frequently brought up the fact that the indigent were not getting adequate care and that if the proposal legislation offered one way of stopping such critics that was the answer.

Dr. Dye recapitulated the advantages of the proposed bill, which he regarded as meriting approval, at least in principle.

After further discussion, the Speaker put the question, requesting all in favor of approving the report of the Committee on Medical Economics, in relation to S. 545, implying that the House of Delegates approves the bill in principle, with the reservation of desiring further elucidation of the methods of administration, to manifest assent by saying "aye."

There was a chorus of "ayes," with two dissenting votes, and the motion was carried.

The Speaker then pointed out that another item in the report required action — namely, the question of veterans' care by the local physician. He asked Dr. Metcalf to explain the question more fully.

Secretary Metcalf read the portion of his report concerning this subject, adding that, with the agreement and the fee table proposed by the Veterans Administration, he had sent to the secretary of each county society the following letter

A special committee appointed by the House of Delegates has formulated the enclosed agreement and fee schedule, which has been accepted by the Veterans Administration, for the care of veterans with service-connected disabilities. The fee schedule is divided into two parts: care in the home office or hospital outpatient department of veterans with service-connected disabilities and that of veterans with service-connected disabilities as inpatients in hospitals. Many patients in the second group will go directly to a Veterans Administration hospital. Some will be inpatients in a local hospital. The Veterans Administration will not be responsible in either group for medical or surgical bills unless the illness is connected with war service.

All members of the New Hampshire Medical Society are eligible to care for veterans under this agreement at these rates. The members who wish to do so should register with Dr Drury, of Manchester, who will send a copy of the agreement and of the fee table and a letter of instructions.

Please present these data at the next meeting of your county society. If you are not having a regular meeting soon, please consider the advisability of calling a special meeting.

Dr Johnston observed that, in accordance with the letter, most delegates should be instructed by the county societies, and that it was the opinion of his society — Cheshire County — that that portion of the report should be accepted.

On a vote taken, Cheshire, Belknap, Carroll, Grafton and Rockingham counties accepted, and Strafford, Coos and Hillsborough counties rejected the recommendation.

Dr Richards, explaining the rejection by the delegates from Hillsborough County, stated that the vote had not been taken until after a long scientific meeting and that some of the members who had left the room had expected to return and take part in the discussion. The president had wished to rush the matter through. The representatives of Nashua and Manchester had rejected the recommendation. Eighteen people had voted, and over a hundred had been present at the meeting. The Nashua County Society later met and expressed its approval of the recommendation.

The Speaker asked if anyone wished to make a motion.

Dr Dube moved that the House of Delegates go on record as approving the fee schedule as given to the different county societies, as well as the program for the care of the veterans with service-connected disabilities.

This motion was duly seconded.

Dr Dunbar pointed out that Hillsborough County had voted against the acceptance of the Veterans Administration fee list, not against the other proposal.

The Speaker then requested the delegates to signify approval or rejection of the program of home-town care for veterans.

There was a chorus of "ayes," with three dissenting votes, and the motion was carried.

The report of the Committee on Medical Education and Hospitals was then presented, as follows:

The medical educational activities within the Society were practically eliminated as would be expected, during the war period. The extension of fellowships granted us by the Commonwealth Fund in previous years were suspended for the duration and there is no information available as yet regarding the fact or date of their resumption.

The Speakers Bureau — a list of volunteers for the presenting of papers for county meetings and previously available to secretaries of county societies — is long since out of date. The membership — now fairly well stabilized after the war — is again being circulated for re-establishment of this list. It is hoped that this will stimulate some original presentations by our own membership and such a list is welcomed by the county-society secretaries.

In this connection the committee registers its support of the Society's Program Committee in its policy to arouse greater interest on the part of the members in presenting a greater portion of the program of the state meeting than they have in recent years. With the increasing numbers of younger men coming into the state, more emphasis should be placed on this phase of the program. Although prominent outside speakers are a necessary and valuable part of a state-society program, the main purpose should be the presentations of its members. Obviously this can be accomplished only with a real interest and willingness on the part of the members.

There have been many developments in the hospital situation in the past eighteen months — some of which have real significance for the future. This concerns the general implications of the participation of federal funds in hospital construction which will in turn introduce similar participation in hospital standards and thereby perhaps, an indirect participation in a program heretofore assumed to be under purely local control.

In the summer of 1945 as previously reported the Governor of New Hampshire appointed a commission for hospital survey. This followed Senate Resolution 191 which appropriated funds for such a survey in each state. The chairman of this committee served as a member of the commission, whose chairman was Mr. James Langley, of Concord. The survey carried out by an efficient and experienced field worker, was completed in the fall of 1946, and the report submitted to the Governor.

Two months ago two bills were introduced in the New Hampshire General Court, where they were referred to the Committee on Public Health and Appropriations. These are House Bills No. 370 and 371.

House Bill No. 371 of the Revised Laws is an act to require the licensing, inspection and regulations of hospitals and related institutions. This act could encompass a wide range of activities and would require annual license. The "licensing agency" is the state health officer.

This bill would set up a hospital advisory council to act with the state health officer. It is important that the same council would perform with the New Hampshire Department of Health in the administration of House Bill 370.

Section 10 of House Bill 371 covers the origin of this hospital advisory council as follows:

The Governor with the advice and consent of the council shall appoint an Advisory Hospital Council to advise and consult with the Licensing Agency in carrying out the administration of this act. The Council shall consist of the head of the Licensing Agency (State Health Officer) who shall serve as chairman *ex-officio* and eight other members, and shall include representatives of non-governmental organizations or groups and of state agencies concerned with the operation, construction and utilization of hospitals including representatives of the consumers of hospital services. Each member shall hold office for a term of three years, except that any member appointed to fill a vacancy occurring prior to the expiration of the term for which his predecessor was appointed shall be appointed for the remainder of such term and the terms of office of the members first

taking office shall expire, as designated at the time of appointment, three at the end of the first year, three at the end of the second year and two at the end of the third year after the appointment. Council members shall serve without compensation but shall be entitled to receive actual and necessary travel and subsistence expenses while serving away from their place of residence. The Council shall meet as frequently as the chairman deems necessary, but not less than once each year. Upon request by three or more members, it shall be the duty of the chairman to call a meeting of the Council.

House Bill No. 370 is an act relative to hospital survey and construction. Section 3, on administration, reads as follows:

The Board of Health shall constitute the sole agency of the state for the purpose of (1) making an inventory of existing hospitals, surveying the need for construction of hospitals, and developing a program of hospital construction as provided in sections 6 and 7, and (2) developing and administering a state plan for the construction of public and other nonprofit hospitals as provided in sections 9 and 15 hereof.

The Hospital Advisory Council, as created under Bill 371, is "to advise and consult with the Board of Health in carrying out the administration hereof." The remainder of the bill has to do with procedures of application, review, approval and so forth.

In general, House Bill 370 is the implementation of the Hill-Burton Act for federal aid in hospital construction.

This act will be administered by the United States Public Health Service on a state allocation basis through the agency of the state departments of health. Exhaustive national hospitalization surveys have been carried out by the Public Health Service. Allocation of funds to states will be based on a formula involving population, per-capita wealth and present hospital-bed availability. New Hampshire participation, as based on these factors, will be relatively small — \$340,000 annually for the next five years.

It is assumed that administration of the act will involve practically some direct participation by the federal government by means of the United States Public Health Service in such matters as state boundaries affecting service areas of many of our institutions, which will involve the development of certain intrastate considerations.

Much could be written on the possible implication of this general movement. This is a brief sketch of the factual information.

JOHN P. BOWLER, *Chairman*
JAMES W. JAMESON
SAMUEL M. BROOKS

Dr. Macmillan then stated that the Committee on Officers' Reports approved this report and recommended it for consideration.

The motion to accept the report was duly seconded and was carried.

(To be concluded)

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

Weekly Clinicopathological Exercises

EDITH E. PARRIS, *Assistant Editor*

CASE 33381

PRESENTATION OF CASE

A fifty-six-year-old man, formerly a lawyer, who had been employed for the previous seven years as a bartender, was admitted to the hospital with a complaint of weakness.

Eight years prior to admission the patient had noticed edema of the ankles following a venous ligation for varicosities. At about the same time he started drinking heavily, consuming about a quart of liquor a day. For about the same period he had experienced nocturia (two or three times). Six weeks before admission there was a rather sudden onset of dyspnea, which became so troublesome that he had to sleep sitting in a chair. He also became tense and shaky and stopped drinking alcohol after this episode. A physician, who had been giving him vitamins and liver extract for about a year, prescribed Purodigin about three weeks prior to entry. On the morning of admission, while still in bed, the patient was seized by a sharp pain

in the left portion of the precordium that was aggravated by deep breathing on moving and relieved after a few hours by the application of heat.

Physical examination revealed a markedly dyspneic man who was slow in comprehending and inaccurate in answering questions. Many purpuric spots were present on the arms and abdomen. The skin was pale yellow. There was marked distention of the veins of the neck and legs. The cardiac impulse was felt 11 cm. to the left of the midsternal line in the fifth interspace. A loud apical systolic murmur was heard. The liver edge was palpable three fingerbreadths below the costal margin. There was pitting edema of the ankles.

The temperature was 100°F, and the blood pressure was 130 systolic, 100 diastolic.

Examination of the blood disclosed a red-cell count of 2,520,000, with a hemoglobin of 5.5 gm., and a white-cell count of 21,150, with 76 per cent neutrophils, the hematocrit reading was 24. Several nucleated red cells and macrocytosis and poikilocytosis were noted on the stained smear. Urinalysis revealed a specific gravity of 1.013 with a +++ test for albumin. The sediment contained 30 white cells and rare red cells per high-power field. The total serum protein was 6.1 gm. per 100 cc., with 2.6 gm. of albumin and 3.5 gm. of globulin. The nonprotein nitrogen was 220 mg., the serum calcium 4.6 mg., the phosphorus 12.6 mg., the phosphatase 8.2 units, the cholesterol 250 mg. and the cholesterol esters 151 mg. per 100 cc. The serum chloride was 92 milliequiv., and the serum carbon dioxide 7.1 milliequiv. per liter. The prothrombin time was 42 seconds (normal, 19 seconds). The cephalin-flocculation test was +++ in forty-eight hours. The

van den Bergh reaction was 14 mg per 100 cc direct and 22 mg indirect. A blood Hinton test was negative.

X-ray films of the chest showed generalized enlargement of the cardiac shadow, the ratio being about 15.26. The aorta was somewhat tortuous, and there were mottled areas of increased density extending out into both lung fields from the hilum. A plain film of the abdomen showed kidneys that appeared to be normal in size and position. The liver was somewhat enlarged. No unusual soft-tissue masses were noted, nor were any unusual areas of calcification seen. The visualized portions of the bones appeared normal. An electrocardiogram showed a rate of 75, a PR interval of 0.17 second, normal axis deviation and diphasic T waves in Leads 1 and CF₁. The T waves were low and upright in Leads 2 and 3 and inverted in Leads CF₄ and CF₆.

During the first thirty-six hours after admission the patient was practically anuric, passing only 75 cc of urine, and 125 cc was passed during the following twenty-four hours. The nonprotein nitrogen was 180 mg per 100 cc., and the carbon dioxide 11 milliequiv per liter. The patient became weak and vomited several times. On the fourth hospital day he was drowsy and the entire body became edematous. The blood pressure was 133 systolic, 95 diastolic. He expired quietly on the sixth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. JOHN W. ZELLER. When I first read this summary I thought that many of the data given indicated the presence of serious disease of the liver. On considering it further, however, I was more inclined to believe that the patient had declined rapidly because of renal and cardiac disease. Probably the strongest evidences in favor of liver disease are the history of alcohol and the presence of jaundice—I suppose that we can accept the yellow skin as representing jaundice, the record does not state that the sclerae were yellow.

DR. BENJAMIN CASTLEMAN. Can you answer that query, Dr. DuToit?

DR. CHARLES H. DUTOIT. The sclerae were yellow.

DR. ZELLER. The elevated bilirubin could have been present on the basis of prolonged elevated venous pressure and liver anoxia. According to the history, this condition persisted for no longer than six weeks, which I consider quite time enough for hepatic changes to have developed. There are other data here, however, that could perfectly well go with a diagnosis of severe primary liver disease. The liver was large, although that could be accounted for in other ways. There may have been changes in the vitamin K metabolism as evidenced by the presence of purpura and a prolonged prothrombin time. These findings, however, also occur

in severe renal disease. The anemia could be explained in a clear-cut case on the basis of liver disease. A physician had been giving liver extract for a year previously, possibly with that in mind. The cephalin-flocculation test, of course, in itself is evidence more in favor of hepatic than of renal disease. The test, however, depends on alterations in globulin, which were present in this case and which also occur in renal disease. It alone probably argues somewhat in favor of liver disease. I am willing to concede that the patient had an abnormal liver, but I do not believe that it led to his rapid decline and death.

From the point of view of kidney disease we have the following pertinent data. It is stated that the patient had nocturia two or three times. That does not seem too important in view of the high alcoholic intake. The anemia is consistent with the anemia of prolonged renal disease, which may occur with either a high or a low color index. The urinary findings are not helpful because there was only one urine examination. It is obvious that the service that treated this man had a difficult problem, because he was comatose and not producing urine well and was certainly not a fit subject for adequate study. The high nonprotein nitrogen and the changes in the blood proteins are also consistent with severe renal insufficiency. The high serum phosphorus, the low calcium and the elevated phosphatase are probably the strongest group of findings that argue for primary renal disease of fairly long standing. How long, Dr. Castleman may be able to tell by the appearance of the bones, because if the condition persists for a sufficiently long time, secondary hyperparathyroidism may take place and actual bony changes typical of osteitis fibrosa result. The changes in the serum chloride and carbon dioxide are also consistent. The x-ray studies suggest the presence of pulmonary edema, which certainly would fit in with the picture of some type of cardiac or renal failure.

From the point of view of heart disease, it is evident that the acute episode that marked the beginning of the terminal illness was something that had to do with the heart or lungs. On the morning of admission the patient had chest pain for the first time, described as a sharp, precordial pain on the left side definitely aggravated by deep breathing and moving. It was relieved after a few hours by the application of heat. Certainly, it seems as if there was some pleural involvement, and the implication at the moment is that this man suffered an acute accident involving either the myocardium or the pericardium and the pleura. He showed definite evidence of elevated venous pressure, with distention of the neck veins, a large liver and edema of the legs followed by generalized edema. The cardiac findings themselves are indicative of a large heart.

So far as consideration of the accident that had taken place in the chest goes, there are not many data to help us in making a diagnosis. One wonders about coronary thrombosis. It seems to me that the white-cell count was too high to be explained purely on that basis, although it is a possibility. Any acute abdominal emergency with chest pain is quite unlikely from the rest of the story. We know, however, that in uremia it is possible for events of that sort to occur and not to be clearly defined clinically.

Dissecting aortic aneurysm is rather unlikely, although I was quite attracted to that diagnosis when I thought of the possibility of involvement of the renal arteries and subsequent oliguria. It would not entirely explain the blood chemical findings, however. The summary does not suggest anything resembling spontaneous interstitial pulmonary emphysema. Pulmonary infarction must be considered. This man had a prolonged prothrombin time, and the veins had been tied off eight years previously. We know that there are some disquieting cases in which venous ligation has failed to prevent pulmonary emboli, but I doubt whether that occurred in this patient.

Other conditions that sometimes occur in patients in terminal uremia are pericarditis with effusion or even septic pericarditis. In this particular case I believe that pericarditis may adequately explain the findings. The rapid onset of dyspnea about six weeks before admission might seem difficult to explain in this way, but cases of pericarditis with effusion and a fairly rapid onset of dyspnea occur. The pain on admission could have been due to pericarditis with some associated pleural involvement. I hope that the x-ray films will give some help on that.

So far as the blood pressure is concerned, a pressure of sufficient degree was maintained to make me doubtful about the presence of coronary thrombosis.

May I see the temperature chart? In the written abstract only one temperature reading of 100°F is recorded. I should have expected a slightly higher temperature with a septic process. None are recorded, and the chart shows a gradual descent during the last three days in the hospital. The fact that the pulse came down is also interesting and is against the presence of uncomplicated myocardial failure. The respirations were steady — around 20 — until they went up to a high figure shortly before death. It should again be pointed out that sometimes the temperature does not indicate the presence of sepsis in debilitated patients with uremia.

May we see the x-ray films?

DR STANLEY M. WYMAN: The enlargement of the heart described is well seen. I cannot say that it is a characteristic configuration. It might be due to pericarditis.

DR ZELLER: Were the films taken in a recumbent position?

DR WYMAN: No, the patient was upright.

There is no evidence of a large effusion in the pleural cavity, but I strongly suspect a small amount of fluid in each costophrenic angle. The mottled density in both lung fields seems to emanate from the hilum and is patchy in character, suggesting edema.

The record states that in the film of the abdomen the kidneys are normal in size and shape. I believe that they are small and also that they are irregular in contour, suggesting lobulation. The liver may be large. The spleen I cannot make out. Dr Zeller raised the question of bone changes, and I might say that the bones do look osteoporotic.

DR ZELLER: That is a real help.

I do not feel like commenting to any great extent on the electrocardiogram. The findings are not particularly indicative of coronary thrombosis. The absence of Q waves is against it. The T-wave changes are consistent with a diagnosis of pericarditis.

DR DUToIT: I might add that a pericardial friction rub was heard.

DR ZELLER: That is also helpful. Is there any other information that I should have?

DR DUToIT: No.

DR ZELLER: From the point of view of the underlying renal disease, we now have an x-ray interpretation that indicates the presence of shrunken kidneys of some sort. So far as polycystic disease is concerned, I should not expect the kidneys to be shrunken and polycystic at the same time. Polycystic kidneys are usually fairly large. I should prefer to consider the presence of chronic glomerulonephritis, chronic vascular nephritis or pyelonephritis, with this picture as an end result. I doubt that the underlying disease was renal tuberculosis or some of the more definite urologic conditions with obstruction, ureteral or prostatic. In such a case I think that more definite information regarding such an obstruction would have been available during the patient's life.

DR DUToIT: The patient was catheterized, and 75 cc of urine was obtained.

DR ZELLER: I rather doubt that the patient had an end stage of amyloid disease of the kidneys. I do not know on what basis it could occur. I have not heard of its occurring with cirrhosis of the liver.

For my final diagnosis I shall have to say that the patient had severe, diffuse, long-standing renal disease — probably chronic glomerulonephritis or chronic vascular nephritis — and pericarditis with effusion. The effusion may have been associated with some bleeding into the pericardium, which has often been described. I rather doubt that it was hemorrhage into the pericardium, however. I originally suspected a septic pericarditis, but since sec-

ing the temperature chart, I am less impressed with that possibility. I also believe that this patient had pulmonary edema and secondary hyperparathyroidism, with evidence of osteitis fibrosa in the bones. I think that it is entirely likely that he had the alcoholic type of cirrhosis of the liver.

DR. WILLIAM W. BECKMAN: Do you care to comment on the blood smear? That bewildered us on the ward.

DR. ZELLER: I can comment to the extent of saying that I too am bewildered by it. I think that a smear of this sort can be associated with the anemia of severe liver disease. I was unable, actually, to find a description of anything like this to fit the picture of anemia associated with severe renal disease. If I were forced to say, I think that it is more consistent with severe liver disease than renal disease.

DR. JACOB LERMAN: The blood picture indicates bone-marrow invasion or blood loss.

DR. DUROI: Dr. Wyman Richardson saw the blood smear and said that it was suggestive of bone-marrow invasion such as multiple myeloma.

DR. BECKMAN: Was Bence-Jones protein found?

DR. DUROI: We were unable to find any by crude test.

CLINICAL DIAGNOSES

Uremia, due to chronic glomerulonephritis
Hypertensive heart disease, with failure
Portal cirrhosis of liver

DR. ZELLER'S DIAGNOSES

Severe, diffuse, long-standing renal disease
(? chronic glomerulonephritis or chronic vascular nephritis)

Uremia
Pericarditis, with effusion
Pulmonary edema
Secondary hyperparathyroidism

ANATOMICAL DIAGNOSES

Acute and chronic pyelonephritis
Pericarditis, acute, fibrinous, uremic
Cardiac hypertrophy
Pulmonary congestion and edema
Central congestion and necrosis of liver
Hydrothorax, bilateral, slight
Ascites, slight
Parathyroid hyperplasia, secondary

PATHOLOGICAL DISCUSSION

DR. CASTLEMAN: Autopsy showed an enlarged heart that weighed over 400 gm. There was pericarditis of the fibrinous type, with a little effusion — 75 cc of turbid fluid — but no sepsis. I believe that it is rare to find septic pericarditis associated with uremia. One sees thick fibrin described as the bread-and-butter type, but cultures are almost always sterile. The coronary arteries were not remarkable.

The kidneys were shrunken, weighing together 150 gm. They showed slight to moderate lobulation, the surface of the kidney between the scars being fairly smooth rather than coarsely granular. At the time of autopsy there were a number of wagers going on regarding what type of renal disease was present. The facts that the kidneys were lobulated and contained yellow areas and that the intervening parenchyma was smooth made one group think that it was chronic pyelonephritis, another group considered it vascular nephritis, and a third group, glomerulonephritis. Microscopical sections, however, revealed some degree of vascular change, but there was marked fibrosis and cellular infiltration throughout the kidneys, both chronic and acute. I believe that the whole process is best explained by chronic pyelonephritis, with some activity still going on. As a result of the long-standing renal disease there was secondary hyperplasia of the parathyroid glands. The bones showed a few areas of early bone resorption such as one might see in long-standing renal disease. The lungs were heavy, weighing over 1000 gm, and showed a fair amount of congestion and some edema. The liver was not enlarged, weighed 1400 gm and on microscopical section showed a severe degree of central necrosis and congestion, such as one might see with failure of the right side of the heart, that is consistent with the engorgement of the neck veins, the pleural fluid — 200 cc in each pleural cavity — and the ascites.

DR. BECKMAN: How about the bone marrow?

DR. CASTLEMAN: The bone marrow showed moderate red-cell hyperplasia.

CASE 33382

PRESENTATION OF CASE

A sixty-year-old nulliparous housewife entered the hospital with the chief complaint of weakness.

Six months before entry the patient had been admitted to another hospital complaining of weakness, nervousness and weight loss of unknown amount. She had had asthma for four years. The thyroid gland was somewhat enlarged, and the pulse was about 110. The basal metabolic rate was recorded at +40 per cent. An eosinophilia of 11 to 19 per cent was present. A thyroidectomy was advised, but the patient desired to delay the operation. Four months later, after being on iodine therapy, she was readmitted, and a subtotal thyroidectomy performed. The pathological report was "colloid goiter with no evidence of hyperplasia." Postoperatively, she was improved until ten days after discharge, when she awoke at 2:00 a.m. with "heaviness" of the right arm. This was followed in a few days by similar sensations in the left arm, the right leg and, finally, the left leg. Weakness

followed, and she became bedridden. Vitamin B injections did not help. No dysphagia was noted. Dyspnea and orthopnea became increasingly severe. No cough, chest pain or gastrointestinal symptoms were observed. Some mental deterioration had occurred gradually during the preceding two years. The patient had had nocturia (four times) without other genitourinary symptoms for several months. The menopause had occurred at the age of fifty-four years.

Physical examination revealed an emaciated, orthopneic woman with soft atrophic muscles. There was dependent edema of the arms, legs and sacrum. The heart rate was regular, with sounds of poor quality. The heart was not enlarged. There was flatness to percussion over the lower right portion of the chest, with diminished breath sounds but no rales. The liver edge was palpated four fingerbreadths below the costal margin. The abdomen was normal otherwise. The pupils and ocular movements were normal. There was no facial weakness. The palate and tongue were normal. Except for slight movement at the shoulder, there was complete paralysis of the right arm and hand. The strength of the left arm and hand was about a fourth normal. The dorsiflexors of both feet were paralyzed, there was little voluntary movement of the right leg, the left leg was somewhat stronger and could be raised voluntarily. The arm jerks were present on the right and absent on the left side, and the knee and ankle jerks were absent, as were the plantar reflexes. Because of the patient's mental status sensory examination was not satisfactory. Pinprick and touch were recognized everywhere but seemed to be diminished over the extremities. Vibration was felt at the wrists but not over the tibiae and malleoli. There did not seem to be a sensory level. A healed thyroidectomy scar was present.

The temperature was 98.6°F, the pulse 120, the respirations 50, and the blood pressure 115 systolic, 75 diastolic.

Examination of the blood disclosed a white-cell count of 33,900, with 38 per cent eosinophils, 4 per cent lymphocytes, 4 per cent monocytes and 54 per cent neutrophils. The urine had a specific gravity of 1.018 and gave a ++ test for albumin but contained no sugar. Four red cells, 6 white cells and a rare granular cast per high-power field were present in the sediment. The urine culture showed colon bacilli and nonhemolytic streptococci. The total protein was 5.84 gm per 100 cc, with an albumin-globulin ratio of 0.85. The nonprotein nitrogen was 35 mg per 100 cc. An electrocardiogram showed a normal axis, the T waves were extremely low in Lead I, flat in Leads 2 and 3 and upright in Lead CF₂. On the next day auricular fibrillation was noted.

X-ray studies showed moderate decalcification of the spine, an area of homogeneous density at the

right base having the appearance of pleural fluid and a calcified area in the region of the right lobe of the thyroid gland.

The patient continued to suffer from dyspnea and orthopnea in spite of digitalis and oxygen. She became aphasic and disoriented and died on the sixth hospital day.

DIFFERENTIAL DIAGNOSIS

DR WILLIAM CLARK. It is not quite clear to me when the patient was admitted to this hospital, but I am assuming that it was about one and a half months after the onset of the sensation of heaviness in the right arm. I should like to separate the course of the illness into three phases, the first being characterized by asthma, the second by weakness, nervousness and loss of weight, and the third by neurologic, cardiac and renal disease. It seems reasonable to me, however, that one dominant pathologic process was responsible for all the manifestations and that the asthma was the first symptom. During the course of this illness a diagnosis of thyrotoxicosis was made, and a subtotal thyroidectomy was performed. In retrospect I believe that it is justifiable to question the diagnosis of hyperthyroidism in spite of the fact that it seemed a logical explanation for the weakness, nervousness, loss of weight and tachycardia prior to operation. Even in the presence of an elevated basal metabolic rate we know that such phenomena are common to many diseases, and fitting all three phases together will give us a more logical explanation for the preoperative symptoms.

The pathologist's report and the postoperative course make the diagnosis of thyrotoxicosis somewhat questionable. Some evidence of hyperplasia should have been found. It is my impression that complete involution of the thyroid gland is not the rule following iodine therapy. Extreme muscle weakness is sometimes encountered on the basis of Graves's disease, even after thyroidectomy, particularly when a large portion of the gland functions outside the neck and is not seen by the surgeon. I prefer to believe, however, that the patient did not have Graves's disease. During the early phases of the illness one might become immediately suspicious of periarteritis nodosa as a possible diagnosis because of the asthma and eosinophilia. The association of these two diseases has been pointed out by Dr. Francis M. Rackemann.* After the operation the patient seemed to have developed a neurologic disease and, in addition, presented fairly definite evidence of involvement of the heart and kidneys. I am referring, of course, to the orthopnea and dyspnea, pleural effusion, hepatomegaly and dependent edema in reference to the heart and to the urinary findings in reference to the kidneys. I shall

*Rackemann, F. M., and Greene, J. E. Periarteritis nodosa and asthma. *Tr. A. Am. Physicians* 54: 112-118, 1939.

pass over the nervous-system involvement for a moment to make some remarks about the involvement of these two systems. Some of the respiratory distress may have been related to the asthma, although wheezing is not mentioned. The low serum protein may have played a role in the edema and may have been related to the liver disease. The pleural effusion could have been a manifestation of heart failure but also may have been associated with serositis. The renal disease consisted of albuminuria and cells in the sediment and perhaps the additional findings of a slight elevation of the nonprotein nitrogen and lowering of the serum protein. I note that there was no hypertension, and I should not consider the renal disease the primary factor.

Without going in detail into the findings in the examination of the nervous system, I shall assume that the only logical explanation is that a polyneuritis developed. The involvement was bilateral and somewhat bizarre, with rather definite sensory involvement.

Such neurologic manifestations are so frequently associated with periarteritis nodosa, occurring in the presence of asthma and a high eosinophilia, that they make such a diagnosis almost compelling. I shall attribute all the manifestations of the illness to a generalized necrotizing arteritis. Other causes of eosinophilia do not seem to fit well, and I shall not discuss them. Some criticism of the diagnosis of periarteritis nodosa may be justified on the basis of the lack of fever and hypertension, but we know that these findings are not always present. Periarteritis nodosa has strange manifestations, and tissue examination is almost always necessary to establish its presence. I should think that tissue removed at the thyroidectomy would not have been helpful in this regard. In addition, postmenopausal osteoporosis and generalized atherosclerosis were probably present, and the latter may have contributed to both the mental confusion and the heart disease.

Dr. ALFRED KRAMER. I was asked to see this patient after an episode of acute peripheral circulatory collapse characterized by marked tachycardia, a fall in blood pressure, sweating and dyspnea. It was at first thought that this represented an idiosyncrasy to barbiturates because a similar episode had occurred postoperatively, when barbiturates had been administered. Additional information in the history, however, ruled this factor out, since it was discovered that the patient had been taking these drugs intermittently for some time.

She was not more extensively studied because during her stay here she remained critically ill. I reached exactly the same conclusion that Dr. Clark did, believing that periarteritis nodosa was the best explanation for the complicated picture presented.

CLINICAL DIAGNOSIS

Periarteritis nodosa

Dr. CLARK's DIAGNOSES

Periarteritis nodosa

Pleural effusion

ANATOMICAL DIAGNOSES

Periarteritis nodosa

Hydrothorax, bilateral

Pericarditis, acute fibinous

PATHOLOGICAL DISCUSSION

Dr. BENJAMIN CASTLEMAN. The diagnosis of periarteritis nodosa is not usually made grossly at autopsy because in most cases the involved vessels are arterioles and small arteries. It is only when the lesions are present in the larger arteries, such as the coronary and the mesenteric, that one can palpate or see the nodularity and beading of the vessel wall. In this case the only suggestive gross findings were some scattered whitish areas in the cortex of the kidneys and a yellowish spot in the interventricular septum. Microscopically, these foci proved to be small infarcts resulting from occluded diseased vessels. All stages of arteritis from acute necrosis of the vessel walls with polymorphonuclear—especially eosinophilic—infiltration to organization of thrombi with recanalization were seen in the heart, kidneys, liver, peripheral nerves and skeletal muscles.

The thyroid gland showed no evidence of hyperplasia or arterial disease. I was unable to find any arteritis in the lungs, but the bronchi contained a great deal of mucus and the basement membranes and muscle walls of the bronchi appeared thicker than normal. These findings are consistent with bronchial asthma.

Dr. KUBIK will tell us about the neurologic findings.

Dr. CHARLES S. KUBIK. When I saw the patient on admission the history of a sudden onset of the weakness of the right arm suggested a vascular lesion. The extent and nature of the motor and sensory involvement pointed to multiple lesions, and that together with a history of asthma, indications of cardiac disease and the presence of eosinophilia made the diagnosis of periarteritis nodosa extremely likely.

At autopsy nothing abnormal was observed in the brain, brain stem, spinal cord or peripheral nerves.

On microscopical examination there was arteritis involving a medium-sized subarachnoid artery of the medulla, although the medulla itself and the vessels within it were normal. In the middle and lower cervical regions of the spinal cord, at two neighboring levels, there were similarly diseased, small sub-

arachnoid arteries in the anterior, median fissure. One of these was probably occluded by thrombosis. There were no indications of infarction or signs of ischemia within the cord at these or other levels. The spinal nerves throughout were normal, and nothing abnormal was found in the cerebrum. The only abnormal finding observed within the central nervous system was axonal reaction of the anterior-horn cells of the cervical and lumbosacral regions of the spinal cord. This change, consisting of swelling and central chromatolysis, is characteristic of peripheral-nerve disease, and the reason for it in this case was quite obvious. There was extensive

arteritis involving the small arteries of the peripheral nerves. None of the affected vessels were thrombosed. There was no actual degeneration of the nerve fibers, the myelin sheaths, although probably slightly abnormal, were essentially intact. It is interesting that there may be a marked axonal reaction even though visible changes in the nerve fibers are slight. The same thing has been true in some cases of infectious polyneuritis.

In the cases of periarteritis nodosa examined here, lesions of the nervous system have not been frequent. I recall another case in which there was severe disease of the peripheral nerves and at least one in which there were lesions of the brain.

COST OF HOSPITAL CARE

THE cost of hospital care, together with that of many necessities of life, has increased to a point where it can be met without sacrifice by only a small portion of the population. This is not surprising when it is realized that even in 1942, a war year, the average income of 84 per cent of the workers in Massachusetts was less than \$3000 a year.¹ Two additional factors contribute to the difficulty: there is an acute shortage of hospital beds, and more and more people, owing to modern advances in the detection of such diseases as cancer, diabetes, nephritis and tuberculosis, require hospitalization. It is true that the cost of hospitalization can be completely or partially covered by enrollment in a prepayment insurance plan, but even the Blue Cross appears to be having trouble

in meeting its obligations. Furthermore, although a patient is entitled to receive or able to pay for hospitalization, it is often impossible to secure a hospital bed, even in cases of emergency. The question arises, What can be done to relieve this situation?

In the first place, steps should be taken to increase screening tests whereby disease is detected before it has advanced to a stage that requires hospitalization and to educate the public regarding the symptoms and signs of various slowly progressive diseases. Much has already been accomplished along these lines in tuberculosis and diabetes, but a great deal remains to be done, both in these diseases and in others.

Secondly, certain types of patients should be encouraged, during the period of study and treatment, to remain in their homes or to take up residence in nursing homes, hotels and boarding houses. This ambulatory type of care is less expensive than hospitalization and can be conducted satisfactorily provided that adequate supervision is maintained by means of office visits or by attendance at outpatient clinics. In the latter, and occasionally in doctors' offices, group instruction offers an inexpensive type of medical care, having proved particularly effective in patients with tuberculosis, neuropsychiatric disorders and diabetes.

Thirdly, as previously mentioned in this column,² hospitals should be urged, at least while the acute shortage of hospital beds exists, to operate on a seven-day week, with service available in operating rooms, x-ray departments and laboratories. This would not only increase the number of available beds but also cut down somewhat on the per-diem cost, owing to the decrease in overhead charges that accompanies operation at full capacity. Furthermore, if personnel were available for this type of service, hospital care could be provided by existing hospitals at a lower cost per patient than could be attained by the construction of new hospitals.

Fourthly, when the patient has been admitted to the hospital, it should be the duty of the attending physician to limit hospital services to the indispensable minimum consistent with adequate study and care, to expedite treatment and to discharge the patient at the earliest possible moment that is

compatible with health. One hospital in Boston has adopted a plan whereby the total hospital charges of diabetic patients requiring medical and surgical care who were discharged during the previous week are shown at the staff visit each Monday. A typical sheet lists twelve ward and semiprivate patients with an average total charge of \$269, exclusive of doctors' fees. Such a procedure should accomplish much in impressing on the physician the need for decision and action.

Finally, it is to be hoped that in the not too distant future the costs of the supplies and equipment that are essential to hospitals will drop to a reasonable figure. Just when this will occur, however, is a question on which the ablest economists refuse to hazard a guess. That this is the chief factor in the cost of hospital care is indicated by the fact that the cost of food, clothing, shelter, fuel and light has risen from a combined index number of 98 in 1941 to one of 149 in 1947.

Hospital costs, as well as the expenses of medical care, must be placed within the reach of all. Only with the co-operative efforts of physicians, hospitals, public-health agencies, organizations underwriting prepayment insurance and government — through full payment for services rendered to the indigent — can this goal be attained.

EPIDEMIOLOGY OF POLIOMYELITIS

ABOUT a year ago there was some discussion regarding the propriety and justification of criticisms in the lay press directed against the manner in which the public-health aspects of infantile paralysis were handled in one of Boston's suburbs.¹ This was merely one reflection of the limited knowledge concerning the causes of epidemics of this disease, the manner in which the causative virus spreads and the efficacy of measures intended to control its spread.

In a recent paper read at the Rocky Mountain Conference on Infantile Paralysis, Sabin² summarized some of the recent contributions to the knowledge of the epidemiology of poliomyelitis. His paper,

in its published form, includes an appropriate and timely addendum in which he presents certain guiding principles that are suggested by the facts thus far accumulated. Practical public-health measures are then offered that are in accord with these principles. These suggestions should be helpful to health officers confronted with an outbreak of this disease.

Reduced to its barest essentials, the epidemiology of poliomyelitis may be considered to be similar to that of other enteric infections in which the causative virus is much more widely disseminated in the community during an epidemic than at other times. The care of patients and the public-health measures should therefore be directed toward limiting contact with and the spread of the virus. It has been shown that this virus is present for only a short time in the throat and more frequently and for a longer time in the intestinal tract and stools of certain apparently healthy people, as well as those of nonparalytic and paralytic cases during the epidemic. The virus may be transmitted to others by intimate contact, contaminated hands and fomites. Spread by the respiratory tract seems to play little if any role. The "filth" flies, however, can be contaminated with the virus and may spread it on to food in infective amounts. On the other hand, there is no evidence that the disease is spread by blood-sucking insects, since the virus is rarely found in the blood.

Some of the specific practical suggestions that Sabin offers in answer to the questions most frequently put to health authorities may be mentioned briefly as follows.

Measures designed to minimize spread by droplet infection do not seem to be warranted. It should therefore not be necessary to close motion-picture houses or churches or to refuse admission of patients with poliomyelitis to general-hospital wards.

The closing of playgrounds, swimming pools and other places where children come into direct contact with one another seems justified. The closing of schools depends on whether it is possible better to avoid contact between children in or out of school. Strenuous exercises are best

avoided during an epidemic, particularly by those who have had known and intimate exposure

As to insect control, measures designed to minimize the contamination of food by flies in stores and in homes and efforts directed at the prevention of the breeding of flies where there may be any exposed sewage are warranted. The mass spraying of whole towns or communities with DDT, on the other hand, is of doubtful value.

Patients with poliomyelitis may be cared for on the wards of general hospitals provided that precautions similar to those used in caring for patients with typhoid fever are carried out, including the handling of their food, linens and excreta.

At home, patients with poliomyelitis should be isolated for at least two weeks, and even an isolation period of four weeks, dating from the first onset of symptoms, seems reasonable. The children of such households and the older members who are engaged in the handling of food in stores or restaurants or whose occupations bring them in intimate contact with children should remain at home for a period of at least two weeks. The same procedure is advocated for children who have been exposed in intimate play with members of an infected household.

Sabin emphasizes repeatedly that all these measures will probably not stop an epidemic, but in so far as they are carried out diligently, they may help at least some persons to escape infection who might otherwise be paralyzed.

It is to be borne in mind, however, that these conclusions and recommendations are based on Sabin's own interpretations of the results of recent experimental and epidemiologic studies. Other interpretations of the same findings are apparently possible and may cause some confusion in the minds of public-health workers. Dauer,⁴ for example, concludes that the spread of the virus is probably through secretions of the oropharynx. His conclusion is based on the observations of a number of investigators that transmission of infection takes place in the interval between a few days before and a few days after the onset of a case, coupled with the fact that the virus has been recovered from

oropharyngeal secretions in a large proportion of cases not longer than four or five days following the onset.

NEW HAMPSHIRE MEDICAL SOCIETY

DEATH

SIKORSKY—Vladimir N Sikorsky, M.D., formerly of North Hampton, died on August 1. He was in his eighty-first year.

Dr. Sikorsky recently received a medal for fifty years of membership in the New Hampshire Medical Society. Two daughters survive.

BOOK REVIEWS

Penicillin in Syphilis. By Joseph E. Moore, M.D. 8th, cloth, 319 pp., with 37 illustrations and 52 tables. Springfield, Illinois: Charles C Thomas 1946. \$5.00.

This book is almost as much a contribution to all general phases of medicine in which penicillin is used as it is an exposition of the specific treatment of syphilis. Anyone wishing to learn something about pharmacology and biology of penicillin can well spend his time with this concise analysis and interpretation of the work of the author, that of his immediate colleagues and that of the associated group studies. Slightly more than a third of the volume concerns the basic knowledge of penicillin; the rest deals with special problems of syphilis and how to combat them with penicillin.

Penicillin, like other specific antisyphilitic drugs is capable of producing shock (the so-called "Herxheimer reaction") and in early syphilis these reactions occur in at least 60 to 70 per cent of cases. Unlike the metallic drugs however, there is no treatment fastness to penicillin. The danger of suppressive doses—as compared with total therapeutic doses—when penicillin is used for treatment of the disease associated with unrecognized early syphilis, is elaborately discussed. There is an excellent exposition of the relation between the time and dosage factors in the over all treatment schedule. This important phase of the treatment of syphilis, which is well known to the syphilologist, is clearly expounded for those who will read carefully.

Weight for weight, penicillin is from two to four times as effective as Mapharsen in the therapy of syphilis in man. Its greatest effectiveness is in early syphilis during the phase of the infection when the spirochetes are in their most active dividing phases. With an aqueous solution a total dosage of 2,400,000 units divided into sixty injections in seven and a half days, seems to be the best schedule for early active cases. It is strongly hinted although not vigorously proposed that ten daily single injections of 600,000 units of penicillin in peanut oil and beeswax is an even more effective schedule.

Gummas respond rapidly to penicillin, seroreaction of latent syphilis is not so responsive. Penicillin is so dramatically effective in preventing congenital syphilis that metallic therapy should be completely and universally replaced by penicillin therapy in pregnancy. The effect is equally dramatic in the management of the infant with congenital syphilis. In cerebrospinal syphilis, penicillin in addition to fever therapy is superior to all other treatment alone, it is as effective as metal and fever therapy and is superior to any metal alone.

This small book is packed with information for the student of syphilis and contains essential material for those who treat syphilis.

Radiology for Medical Students. By Fred J. Hodges, M.D., Isadore Lampe, M.D. and John F. Holt, M.D. 8th, cloth 424 pp. with 103 plates. Chicago: The Year Book Publishers Incorporated 1947. \$6.75.

This monograph offers a basic approach to the problem of x-ray diagnosis and therapy without attempting to provide

details in all the ramifications of radiology. The authors provide only a short discussion of the theory of the roentgen ray and brief descriptions of the apparatus, enough to make the theoretical concepts understandable. The technique of obtaining films are discussed only from the point of view of what one can expect to gain from the usual views of each region. The object of the book is not to make a roentgenologist out of each medical student who reads it, but rather to give him enough knowledge so that no matter whether he becomes a general practitioner or a specialist in any field, he will be able to utilize x-ray technic to its full extent and at the same time to recognize its inevitable limitations. The illustrations are ample in number and excellent in quality and follow along with the text so that they are easily available for study. About a third of the text is devoted to radiation therapy, which is rarely discussed in specific detail, rather, space is devoted to the general theoretical and clinical principles involved. For those who desire further information on any subject, an excellent bibliography follows each chapter. This is a book that every medical student would do well to own.

Whether Medicine From dogma to science? By Antony Fidler, M.D. 12°, cloth, 115 pp. Edinburgh Thomas Nelson and Sons, Ltd., 1946. 6 sh.

In this monograph the author, who is a docent of medicine of the University of Warsaw and is at present senior lecturer in medicine at the Polish School of Medicine in Edinburgh, offers a philosophical criticism and evaluation of the present scheme of what he terms "causal medicine." As an alternative, he suggests a system of diagnosis, prognosis and treatment called "the medicine of probability," based on analysis, by the experimental method, of comparative data from large groups of cases. He illustrates the application of this new scheme in medicine by examination of several thousand cases in seven tables in an appendix. His concept, contention and method seem those of the statistician rather than those of the clinician or physician, his paradoxical theory is interesting, but not immediately convincing. It may be questioned whether the medicine of probability would really be more scientific than causal medicine. Perhaps, in spite of the author's statements, medicine is still more an art than an exact science. He himself agrees that "the strength of the personal impressions of a physician grows with his experience, and that is perhaps why older physicians are more inclined to rely upon their clinical 'flair' than upon the results of laboratory findings, and it must be admitted that they are less often mistaken as to their patients' fate than those who place their faith in the findings of the laboratory."

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Charles Darwin and the Voyage of the Beagle. Edited by Nora Barlow. 8°, cloth, 279 pp., with twelve plates, 1 portrait and 1 map. New York Philosophical Library, 1946. \$3.75.

This biographical study is based on twenty-four small, informal unpublished notebooks of Darwin, and thirty-nine letters written by Darwin to his father and sisters, here published in their entirety for the first time. Eight of the letters were previously published in part in the *Life and Letters of Charles Darwin*, by Francis Darwin.

The first part is a short sketch of the life of Darwin, dealing especially with the incidents leading up to his joining of the Beagle expedition. The second part comprises the letters and notebooks. These personal notebooks, written mostly after working hours, throw an interesting light on Darwin's processes of thought. A good index concludes the volume.

Proceedings of the Charaka Club. Volume XI. 8°, cloth, 243 pp. New York Richard R. Smith, 1947. \$7.00.

This new volume contains a selection of papers read before the club during the years 1940 to 1944. Boston physicians are represented by five papers by Dr. Fred B. Lund, one in

conjunction with Dr. Cecil K. Drinker. Lists of present and past members and unpublished material precede the papers. A number of the contributions are short biographical sketches of deceased members, including George L. Walton, by Dr. Lund, and Walter R. Steiner, by Dr. Rufus Cole.

Surgical Pathology. By William Boyd, M.D., M.R.C.P. (Edin.), F.R.C.P. (Lond.), LL.D., F.R.S.C., professor of pathology, University of Toronto. Sixth edition. 8°, cloth, 858 pp., with 530 illustrations, including 22 in color. Philadelphia W. B. Saunders Company, 1947. \$10.00.

This authoritative textbook, first published in 1925 and last revised in 1942, has again been revised. A new section has been added on the pathology and pathologic physiology of congenital heart disease. New material includes tumors of the larynx, pinealoma, Bittner's milk factor in relation to breast cancer, avitaminosis in cancer of the mouth, the Papanicolaou vaginal-smear method in the diagnosis of carcinoma of the cervix, fibrous dysplasia of bone, inflammatory nodules in chronic arthritis and fibrositis of the back. The book is recommended for all medical libraries and as a standard text on the subject.

PRESENTATION OF THE HENRY JACOB BIGELOW GOLD MEDAL

INTRODUCTORY REMARKS AND PRESENTATION OF THE MEDAL*

JOE V MEIGS, M D †

BOSTON

THIS evening we meet to do honor to one of our own Elliott Carr Cutler received his degree in 1913 from Harvard Medical School, where he was a member of the Boylston Medical Society, Alpha Omega Alpha Society and the Aesculapian Club. Thus, characteristically, at the start of his medical career he was a member of the school's literary society, its honor society and its social society. After graduation he went to the Peter Bent Brigham Hospital as surgical house officer. Before the United States entered World War I he was a member of the Harvard Unit, serving with the British Army. On his return to this country he served as resident surgeon at the Massachusetts General Hospital. He then became alumni assistant in surgery at Harvard Medical School and voluntary assistant to the Rockefeller Institute of New York. When the United States entered World War I he joined the Medical Corps of the Army, starting as a lieutenant, but as might have been expected, he was later promoted to captain and then to major. At the end of his military career in the Army, he became resident surgeon at the Peter Bent Brigham Hospital, serving from 1919 to 1921. He subsequently became an associate in surgery at Harvard Medical School. In 1924 he accepted a call to the professorship of surgery at Western Reserve University School of Medicine and was also appointed director of the Surgical Service of the Lakeside Hospital. Here he served with distinction, and one has only to inquire of those who knew him in Cleveland to hear of the great changes and advances that he wrought while there. In 1932, on the retirement of his former chief, the great Dr. Harvey Cushing, he was called back to Harvard Medical School to become Moseley Professor of Surgery and surgeon-in-chief at the Peter Bent Brigham Hospital. It was during that time that

he advanced the knowledge of surgery of the heart by his work on the thyroid gland and its relation to heart failure and by the first operation done directly on the valves of the heart to relieve the crippling effects of mitral stenosis. At the Peter Bent Brigham Hospital he produced much original work, but even greater and more lasting than his scientific contributions was his influence on the young surgeons who were so fortunate as to be trained under him. His enthusiasm and his dynamic personality, as well as his profound knowledge of surgery, left their mark on all his students.

In the summer of 1940, immediately after the fall of France, he reorganized Harvard University Base Hospital No. 5. He was farsighted enough to see that in 1940 we had best be prepared. It was natural that with the outbreak of World War II he should have been appointed by the Governor of the Commonwealth as director of the Medical Division of the Massachusetts Committee on Public Safety. Meanwhile, having maintained his connection with the Army as a member of the Medical Officers Reserve, he had been advanced from major to colonel. On July 18, 1942, he was ordered to active duty and immediately became chief surgical consultant, European Theater of Operations. To comment on his accomplishments during that time is unnecessary. All who served under him know what an enormous influence for better surgery he was and how remarkably he improved and aided in the organization of our extremely efficient Medical Service. He was one of the few medical officers who entered for the emergency who was recognized by promotion to the rank of brigadier general.

During his tour of duty in Europe, he visited the medical services in all unoccupied territories and had the great honor of visiting with the Russian Medical Corps. His Army work accomplished, he returned to his old position as Moseley Professor of Surgery, Harvard Medical School, and surgeon-in-chief of the Peter Bent Brigham Hospital.

*This and the succeeding paper comprise the addresses delivered at the presentation of the Henry Jacob Bigelow Gold Medal at a meeting of the Boston Surgical Society, Boston, June 2, 1947. The recipient of the medal, Dr. Elliott C. Cutler, died on August 16, 1947.

†President, Boston Surgical Society

In 1947 he was appointed acting assistant medical director for the Professional Services Division of the Veterans Administration. His work in this field has been superb. A comparison of the veterans hospitals of today with those of yesterday offers a real idea of the value of this contribution.

He has in his life, as one look at his record shows, done extremely important work in surgery, in research and in teaching. He has found time to belong to a great many civic organizations and may be considered a great public servant. He has been made a member of nearly all surgical associations and clubs and has been honored and decorated not only by his own government but also by those

of England, France and Norway. There are few physicians in our time who have done more work, who have taught more delightfully, who have inspired more young men and who—in spite of a full and busy life—have given more time and work to civic pursuits. And few have given more to their country.

Many are the reasons for presenting the Bigelow Medal to Dr. Cutler, the greatest being that he is the embodiment of the many things that most young men aspire to be.

It is an honor to the members of the Boston Surgical Society to present this medal to you, Dr. Cutler.

THE EDUCATION OF THE SURGEON

ELLIOTT C. CUTLER, M.D., Sc.D. (hon.)*

BOSTON

I AM highly sensible of the great honor done me tonight by the Boston Surgical Society through this presentation of the Henry Jacob Bigelow Gold Medal. As one who has attended the presentation of this honor to all previous recipients—ten during the past twenty-five years—and who knows the unusual gifts and attributes of my predecessors, I am overcome with my own inadequacies. Indeed I have done little more in surgery than many of my own age group in Boston. At the same time, I deeply regret that because of difficulties beyond my control, I have been prevented from giving the time and energy to this oration that the occasion richly justifies. Certainly, no greater honor can come to an American surgeon.

I hope that I shall be forgiven if, in introducing my topic, I utilize in part personal experiences that perhaps explain my way of thinking. In fact, the story of my “breaks” with traditional surgical education in Boston is a reason for the very use of my topic, and may have played a larger part in this generous presentation of tonight than is imagined. When I was a medical student, the fourth-year courses were entirely elective, and although a few brave spirits had hidden themselves away in some special laboratory for as long as six months of this last year and, perhaps, in one or two instances for a whole year, this was not considered the proper way to achieve entrance to the better hospital services. During my third year in the medical school, however, I made up my mind that I was to see plenty of surgery in my lifetime and, therefore, should not devote a valuable year to clinical surgery, particularly under the hodgepodge monthly-assignment system then in vogue. Dr.

Harvey Cushing, who had already started to guide my errant steps, urged me to put in a year with Dr. Walter Cannon, and although all medical students of my age admired and loved Walter Cannon, as all men did who came to know him throughout his long and productive life, I had come under the influence of Dr. Councilman, professor of pathology at Harvard Medical School, and elected to spend my fourth year with Dr. Frank B. Mallory in his laboratory at the Boston City Hospital. I suspected that many of my teachers, especially the practicing surgeons of Boston, thought that this was a rather foolish enterprise. Yet, as I look back on that precious year, it probably did more for me as a budding young medico than any other year in my lifetime, for with Dr. Mallory I learned the value of precise work and the importance of making and recording correct observations, and I learned to enter the domain of books, for there is time in the life of the laboratory worker to read and study and thus to become aware of the immense amount of knowledge available to the profession. And, finally, I learned some pathology. This is one of the cornerstones of surgery, for if the surgeon cannot tell, let us say, inflammation from tumor in the midst of a perilous abdominal procedure, he can never become a really competent surgeon and is nothing more than a handicraftsman. Moreover, it was this year with Dr. Mallory that led me to spend the next nine months in Krehl's laboratory in Heidelberg, working on a problem that involved pathological disciplines as well as surgery and medicine.

I broke with tradition in this city when I selected the new Peter Bent Brigham for my surgical training. This for me was merely the fulfillment of an ambition to work with Dr. Cushing, who had made,

*Moseley Professor of Surgery, Harvard Medical School, surgeon-in-chief, Peter Bent Brigham Hospital.

early in my medical-school days, an immense personal impression on me. I had already determined to go to Johns Hopkins to work with him after graduation from medical school, only to find that he was coming to Boston. This prevented a change of environment that I had hoped might broaden my medical horizon. After an internship at the Brigham Hospital and a sojourn in a military hospital in Paris, I was most grateful to the Massachusetts General Hospital Staff for accepting me, in 1915, as resident surgeon. There I greatly benefited from the example and opportunity presented to me by the senior members of the West Surgical Service, especially Drs. George W. W. Brewster and C. Allen Porter. This interchange of house staff between the two hospitals was the innovation of a happy custom.

After a year at the Massachusetts General Hospital I again broke with tradition, incurring this time the disapproval of my beloved chief and mentor, Dr. Cushing, by moving to the Rockefeller Institute and studying immunity under Dr. Simon Flexner. I had been offered the privilege of taking over the Hunterian Laboratory at Johns Hopkins by Dr. Halsted, but I came to believe that if I did that I should still be in the environment of clinical colleagues, because so many of the young surgeons there were already friends of mine, and I wished to keep away from the clinic as much as possible so that I could benefit from the stern discipline of a meticulous laboratory worker. I well remember the alarm and even disapproval in the minds of several older surgeons in Boston, who were friends of my family and to whom I had often gone for advice, when I told them I was to study immunity. A leading surgeon of that day asked for information concerning the topic and told me he had never had cause to use such information in his practice!

Then followed World War I and its tremendous experience both in traumatic surgery and in the handling of multitudes of patients. In that war I was privileged to be chief of the professional services in an evacuation hospital and although a lowly captain, taking over from a full colonel in the regular Army, I managed to weather the storm and benefited greatly from the administrative experience of trying to keep a large hospital going all the time, up the line, in the mud, without supplies or much assistance. To be sure, I pilfered liberally from the battlefields, but I rarely complained to headquarters, perhaps because I dared not confront high-ranking people, which left me in the good graces of the chief surgeon of the Theater.

After the war there were further years of training at the Brigham Hospital. Nine years after I had graduated from medical school, I quitted the post of resident surgeon at the Brigham Hospital, becoming a junior member of the staff and spending most of my time in the Surgical Laboratory, studying

cardiac surgery. Seen in retrospect, such a bringing up separated me and my ambitions from most of my contemporary colleagues. That I did not know when and where I should settle into an academic life did not seem to bother me at the time, for I was busy and happy in the laboratory. Meanwhile, the Rockefeller full-time plan had just begun, and although it had followed the voluntary full-time arrangement set up by Drs. Christian and Cushing at the Brigham Hospital, it had attracted many followers. I recall long discussions with Dr. Francis W. Peabody and remember that we both believed that there might be certain drawbacks to the Rockefeller system in that the teachers and the men to come under the plan would be robbed of the opportunity to care for their own patients—an important matter, which they were supposed to be able to teach to their students. On this basis I am sure, both Dr. Peabody and I, at that time and later, turned down the Rockefeller full-time system.

The next year, 1923, was a hectic one for me because two medical schools offered me professorships and another discussed the matter with Dr. Cushing and myself, but having taken a look at the candidate, never reappeared. Finally, in 1924, the School of Medicine of Western Reserve University, in Cleveland, made me an offer. The opportunity seemed excellent, and the die was cast. That school, moreover, accepted the so-called "Harvard full-time plan," which was what I desired. No previous clinician had had his office within the walls of the Lakeside Hospital, and when I took over some of the private ward rooms for offices for myself and my young colleagues, it created quite a disturbance. Moreover, I had demanded a good laboratory, and that led the school to more of a financial outlay than perhaps it had anticipated.

The difficulties of transplanting one's self and one's family to a strange city were finally surmounted, although it took several years for the local profession and the populace to realize that the young professor was fit to conduct surgical procedures on men as well as on dogs. It had been rumored about Cleveland before I came that I was an excellent laboratory investigator and knew about the surgery of animals, but had had little experience with man. Even this difficulty, however, had its beneficial side, for it forced me to stick to my laboratory and my wards and to teaching, and to leave the practice to my older colleagues, who were thus made happy and who became eventually my warmest friends and supporters.

Thus, by my early preferences, my training and my first experiences in a clinic of my own, I was directed toward a truly academic life, and tonight I shall speak of the training of the surgeon. Whether or not I have profited by consistently following a course that has for so long been the subject of my thoughts and ambitions, you shall be the judges.

The education of the surgeon really does not begin until he leaves medical school. Yet teachers in graduate schools must consider the early education of the student material handed on to them. It is always to be regretted that in the primary schools little thought is given to the scientific method. All early education is either logic (mathematics) or memory, and memory is the simplest of intellectual functions. And it has seemed a pity that the student's powers of observation and the synthesis of ideas should not have been given some practice. Moreover, postgraduate educators must rely on the medical school for the proper teaching of the medical laboratory disciplines. The surgeons have long decried the diminishing emphasis on anatomy, and now they must worry about the amount of pathology and bacteriology given to their students. Are medical students aware that every operation is an experiment in bacteriology, and are they well grounded in physiology? In my opinion, the medical-school education should be sufficiently broad and sound to allow the student to enter at once into his training as a surgeon. I decry the value of the rotating internship year, now so widely proposed throughout this country, in the education of the surgeon. To my mind, it is merely adding another year to a young man's period of study when he should be getting on with his career. I have long held that the fourth year at the Harvard Medical School is as good as any rotating internship in the country and that students are ready to begin their studies as medical or surgical workers in the broad sense from the moment they leave school. Other Grade A schools are in a similar position. Life is short enough without forcing on the young doctor this additional year, which he cannot well afford, he must some day be prepared to support himself and a family. Moreover, when the student makes up his mind whether he is going into medicine or surgery, — and he can put off a narrower specialty in either of these fields until a later date, — he is wise if he studies the whole hospital plan of the institution where he is to be an intern and is sure that he can acquire there his complete surgical education. This means at least five and usually six years. By that time, he should be fully qualified in the technical art of surgery, should have had enough experience to be proficient in the handicraft side of surgery and, by having been given responsibility as a resident surgeon, should have developed confidence in the practice of his art.

I also wish to emphasize the importance of such an education's being acquired under a single master. Young surgeons who change hospitals frequently never stay long enough to evoke the final interest of the chief surgeon, and since this education is essentially the apprenticeship method, much that is best is lost. It should be pointed out that the education of the physician and that of the surgeon

differ essentially in that although many may profit from the medical examination of a patient with a cardiac murmur or some unusual medical sign, only the person who himself conducts the operative procedure can fully benefit from that experience. This handicraft aspect of surgery is something that must be learned, and it must be learned under the most careful tutelage. The young surgeon finally reaches the point where he must be given individual surgical responsibility and the opportunity to operate independently. Only by such practice can he acquire confidence, which is essential to his final development.

The internship should occupy about eighteen months and should be a graduated system in which the beginner progresses from little responsibility to greater responsibility. Thus, he can begin as a worker in the clinical laboratory and finally progress to senior intern on the ward, with perhaps the most junior intern under him, where he is early given the responsibility as a teacher that is a healthy experience. Those who teach are apt to be most thorough, for to teach one must know the subject, which cannot be glossed over before students in the hope that they will assimilate something that has not been told to them. Moreover, this internship year should give him experience not only in general surgery but also in most of the surgical specialties, and the young surgeon must therefore go to a hospital where all aspects of surgery are covered and preferably where they are grouped under the chief surgeon and go into a common internship experience. This year is also rendered more profitable if toward the end of the tour of duty he works in an outpatient department and has the opportunity to care for ambulatory patients who are his direct charge and responsibility and who come back for observation or further study as he directs. While working in the outpatient department he should be under the careful guidance of staff members as well as the residents on his own service, for here he will achieve experience in conducting himself as in his own office practice in the years shortly ahead of him. It is proper to remark that the appointment of an intern is the most important responsibility of the staff of a hospital. If the material chosen is good, there will be a happy house staff and an excellent *esprit de corps*. Moreover, if the interns are competent, the better ones chosen to be assistant residents later on will be of superior caliber, and as the weeding-out process continues, excellence always remains. To draw good interns means close association with medical students, working hard over clinics and all student engagements, and having it generally known that at such and such a hospital the members of the house staff are well treated, carefully guided and always helped when in need. If a hospital is drawing good interns, it usually means that the staff

has been working hard with medical-school responsibilities

After the internship he should move on to an assistant resident's post, which should occupy about two years and cover periods of four months, at least, in genitourinary surgery, neurologic surgery, orthopedic surgery and gynecology, as well as a major part of his time on the general surgical wards. I hope that while in his major period on the general surgical wards he would have some experience with thoracic surgery, plastic surgery and other less well defined or even narrower surgical specialties. This period as assistant resident should bring the embryo surgeon into close contact with the entire domain of surgical endeavor. It should disclose to him the limitations as well as the possibilities of surgery as a therapeutic agent. His proficiency in the handicraft aspect—what I have called the art of surgery—will greatly increase, and by the end of the period he should be able to perform with safety most of the standard surgical procedures. Such a system for an assistant residency in surgery is again, as with the internship, better if the incumbents begin at intervals of three or four months and then move on into the successive stages of their training as new incumbents arrive. Such a rotation and succession gives to the hospital one man about to complete his service who should be capable enough to substitute for the resident surgeon when he is off duty and thus leave the hospital always well protected. In fact, it is wise to call attention to the fact that any system providing better care of the patients is always the better system—for the pupils, as well as for the patients. Moreover, such a progressive system leaves it incumbent on the senior members of the house staff to teach the newcomers to the service. Here, again, an advantage is achieved both for the patients and for the men in training. A sense of responsibility is developed by this teaching opportunity, and willy-nilly the pupils grow in stature, ability and reliability. After twenty-three years as a professor of surgery, I am convinced that nothing is better for the pupil, as well as his ogre-eyed master, than the steady development of this sense of responsibility. Once it is inculcated in the intern and then polished in the assistant resident it blooms with great vigor and is the major magic in a satisfactory *esprit de corps*.

Having completed his assistant residency, the young surgeon has had three and a half years of sound training in a school for surgery using a common and standardized technic, which is better than if he had served his internship in one hospital, using one technical method, and then moved for his assistant residency to a second hospital where quite a different technic is practiced. Changes of hospital tend to confuse the budding surgeon. He has little knowledge by which to judge which is the better technic and thus may find himself later on practicing a less desirable technic or one that,

because he was not deeply enough trained, he does not practice well, with the result that he finds himself a second-rate technician rather than a first-class one. Nevertheless, when the surgeon has put in his three and a half years, the next step should be a year in a laboratory.

This laboratory year is the critical turning point in the career of the young surgeon because, for the first time, he really begins to think independently. Here, medical training has another aspect that differs from surgical training. The surgical interns and assistant residents are apt to be so busy with important, often life-saving, measures that they do more or less what they are told to do and rarely have the time to sit down and think out exactly why they should do a thing or read up on a topic to see that it is proper. The physician, after his morning rounds, does not have to go through three to five grueling hours of physical labor in the operating room applying his therapy, for his therapy has long since been written in the order book. Therefore, with plenty of time to discuss matters, he can sit down and read up on subjects that have been brought up and that he questions. The surgeon is too busy for such relaxation and education, or perhaps he is physically too tired and cannot force himself to hours of study when that is what he needs most. I have long regarded a year in the laboratory as the period that rapidly differentiates growing young surgeons and in which one can soon pick the good, the bad, the indifferent and the exceptional men. The young surgeon, coming from a busy life in which each moment has been dictated by necessity, is often downcast and depressed when put in a laboratory by himself, particularly so if he is left alone and not helped. He feels lost, as if there were nothing to do. But this is the vital point in his career. He must be left alone because he must learn to think for himself. He has been given a problem but does not seem to know how to go about it. It is unwise for even the most generous teacher to help his pupil at that time. Once the young man has learned to think out a problem, stand on his own feet and go to the library and read books, he bursts into his chief's office full of new ideas, and the world is a different place for him. From then on his chief can work with him as much as he wishes in the laboratory, and the two will have great fun together. But the teacher must not do this too early or before the pupil has learned to think and study, lest he injure the pupil's career and his ambitions. It is remarkable how rapidly the young man develops at that time. And at the end of a year that, ten months previously, had seemed so hopeless, he often begs for another year in the laboratory, a request that often cannot be granted because he is needed to become the resident surgeon and to carry on the full responsibilities of running the hospital.

Thus, at the end of four and a half years the surgeon is well trained. He has acquired the technic and the handicraft of surgery, and he has learned how to think. The momentous changes may never be known to anyone but his chief, but the latter will recognize that the change has occurred and that another safe surgeon is ready to carry the torch.

I have spoken as if the product was complete and finished. That is not fully true, although the young surgeon will do well anywhere with the training he has obtained. But this man can be better prepared by being given greater experience and responsibility. This is especially true if he anticipates leading the life of the teacher and investigator in surgery. I pointed out above that only one person receives full benefit from an operative procedure, and that is the surgeon conducting the operation. As an intern, a few simple surgical procedures can be given to the young surgeon under guidance, while he is assistant resident; more procedures should be permitted him, and he can safely conduct the simpler ones without assistance but not the greater procedures, which therefore should not be completely relegated to the young surgeon. It is true that the assistant resident surgeon at the end of three and a half years in a good clinic should be so well grounded in the principles of surgery that he can conduct any procedure well. Indeed, in the recent war I watched with delight surgeons only three or four years out of medical school conducting the most complicated thoracoabdominal procedures with complete assurance and great technical polish. A final year in the hospital as resident surgeon will give to the assistant resident surgeon all this assurance and polish and will leave him time to begin to put together his first medical contributions. All teachers should wish to propagate their kind and to leave pupils who can occupy chairs of surgery with distinction. The exceptional man will therefore be chosen by his chief to be the resident surgeon at the hospital. This person represents the attrition of the original young graduates who began together as interns and who saw their first losses when the assistant-resident posts were granted.

The resident surgeon is the head of the house staff. He directs the work of the interns and assistant residents and continuously instructs them; he admits and discharges surgical cases, keeps a watchful eye on the outpatient department and may even advise the laboratory fellow, for all who are not staff members fall under his authority. He is held personally responsible by his chief for the care of all seriously ill patients and must report immediately on all accidents or untoward occurrences on his service. With the visiting staff, he sets the schedule of operations and picks those that he wishes to do. At night he uses his judgment whether to call in a staff member or perform the necessary operation himself. And all the time he is responsible for organizing the undergraduate teaching and for informing staff members of their engagements with students. This is a wide scope of responsibilities, but on its successful performance depends the smooth functioning of the service. After a year or two of such responsibilities, the resident surgeon has absorbed all that a position on the house staff can give him. He may go out to settle in practice or to work up on a senior staff elsewhere, or he may be chosen by his chief to join the senior staff in the hospital where his training began. This resident surgeon represents the finished product in the education of the surgeon. He has been given exceptional experience and great advantages. On his shoulders rests the responsibility for educating another generation of surgeons.

* * *

My story is incomplete, but in handing it on to others I can only hope that they will achieve the happiness that has been mine in the devotion and success of pupils. No way of life can bring greater satisfaction than that which comes to those who enjoy teaching and have the rare privilege of being kept young by disciples. In closing my part of this ceremony I wish to thank the members of the Boston Surgical Society for the great honor that they have this evening given to me.

WEIL'S DISEASE*

A Report of Twenty-Three Cases

E CRAIG HERINGMAN, M.D.,† AND JACK H. PHILLIPS, M.D.‡

NEW ORLEANS, LOUISIANA

ALTHOUGH Weil's disease is frequently mentioned in various classifications of the causes of jaundice, it has attracted little attention as a condition that can simulate an acute surgical condition of the abdomen. This is not at all surprising because the disease is generally considered to be quite rare in this country. In fact, state and city health departments have only recently become equipped to undertake the proper diagnostic laboratory procedures.

We became interested in this problem during a review of cases of jaundice at Charity Hospital of Louisiana in New Orleans, in which it was found that operations had been performed on 2 patients who subsequently proved to be suffering from Weil's disease. Further investigation revealed that in the six-year period from June, 1939, to June, 1945, a total of 23 cases of Weil's disease were diagnosed and treated correctly. In 1943, Bruno, Wilen and Snively¹ reported 15 of these cases. Such a large group of cases affords a unique opportunity for the study of this specific infection.

The usual problem in the jaundiced patient is to decide whether the jaundice is obstructive, hemolytic or hepatogenous in origin, and whether operation is indicated. The difficulty in the differentiation of these types of jaundice has been considerably reduced by the newer concepts of liver physiology and bile-pigment metabolism. Steigmann, Popper and Meyer² have shown that the correct diagnosis can be made in 95 per cent of patients by careful clinical observation, prolonged study of the urinary excretion of bile pigments and judicious use of liver-function tests.

A case of Weil's disease, however, may turn out to be a diagnostic problem during two separate and well defined stages in the course of the illness. In the incipient or so-called "septicemic phase," the clinical picture can mimic an acute surgical condition of the abdomen so closely that operative intervention is deemed essential. On the other hand, once the second, or icteric, phase of the illness has developed, it must be recognized that the jaundice is not obstructive in character and that surgery is contraindicated. Diagnosis during the second stage of the disease is relatively easy because there is usually sufficient time to study the patient and to determine the results of the various laboratory tests required to establish the true nature of the illness.

It is evident, therefore, that the greatest difficulty in the correct diagnosis is in the prejaundice phase of Weil's disease, when the symptomatology is variable and misleading. This is borne out by the fact that the only patients in the series who were subjected to surgery were operated on during the early stage of the disease before jaundice was evident. Surgical consultations were requested for 5 additional patients, but in each case jaundice was present and additional laboratory procedures were recommended to establish the diagnosis.

Once these facts became apparent, it was considered worth while to review in detail the 2 operative cases and to discuss the clinical aspects of the other 21 cases to stimulate interest in this disease.

CASE 1. E. J. F. (T-40-43067), a 38-year-old housewife, was admitted to the hospital on April 20, 1941, with the complaints of colicky pain in the upper abdomen, nausea and vomiting, a high temperature and backache. These symptoms had begun about 2 days previously, and during the interval severe epistaxis had occurred.

Physical examination revealed a well developed well nourished woman who appeared acutely ill. No abnormal findings were noted on examination of the heart and lungs. Palpation of the abdomen revealed tenderness in the right upper quadrant. The liver edge was thought to be barely palpable, and voluntary guarding of the abdominal muscles was noted.

The temperature was 104°F, the pulse 116, and the respirations 24. The blood pressure was 128/68.

Examination of the blood disclosed a red-cell count of 4,500,000, with a hemoglobin of 70 per cent, and a white-cell count of 19,600 with 86 per cent neutrophils, 12 per cent lymphocytes and 2 per cent monocytes. The urine had a specific gravity of 1.008 and gave a + test for albumin, but contained no sugar or bile. Microscopical examination of the sediment revealed no cells or casts.

A provisional diagnosis of acute cholecystitis was made. The patient was taken to the operating room on the day of admission, and cholecystectomy was performed. At operation the gall bladder was slightly distended but showed no evidence of inflammation. The liver was moderately enlarged.

During the 1st week after operation the high temperature continued, and the patient suddenly developed marked jaundice. On May 3 the icteric index was 36, and the blood urea nitrogen 36 mg. per 100 cc. Agglutination for *Leptospira interrogans* reported by the United States Public Health Service was 1:5000 on May 2 and 1:30,000 on May 6. Supportive therapy with 5 per cent dextrose infusions and blood transfusions was promptly instituted. During the third week of illness the jaundice diminished. An uneventful recovery followed and the patient was discharged on May 20.

The history and physical examination in this case justified the diagnosis of acute cholecystitis. There were practically no early indications of the true nature of the disease except the backache and the possibility that the nosebleed was a manifestation of the hemorrhagic tendency often present in Weil's disease. The temperature of 104°F was higher

‡Intern, Charity Hospital of Louisiana.

than is ordinarily expected in the usual case of uncomplicated early cholecystitis. When jaundice developed, the possibility of a common-duct stone overlooked at operation was considered. This was ruled out rather promptly, however, by various laboratory tests.

CASE 2 E G (I-42-60881), a Negro, was admitted to the hospital on August 30, 1942, with a history of an illness of 3 days' duration. Malaise and anorexia were the primary symptoms, but the patient soon developed pain in the right upper and lower quadrants of the abdomen. Nausea and vomiting occurred frequently during that time, and a cough also developed.

Physical examination disclosed a patient who appeared acutely ill. The heart and lungs were clear to percussion and auscultation. The right side of the abdomen was tender, especially in the right lower quadrant. No rebound tenderness could be elicited, however, and only voluntary rigidity was present. The liver was described as being palpable.

The temperature was 102°F, the pulse 100, and the respirations 25. The blood pressure was 105/60.

Examination of the blood disclosed a red-cell count of 4,300,000, with a hemoglobin of 11.5 gm., and a white-cell count of 12,500, the differential count showing a shift to the left. The urine had a specific gravity of 1.012 and gave a + test for albumin, with no sugar or bile and a trace of urobilinogen. The sediment contained occasional red cells and white cells.

A tentative diagnosis of acute appendicitis was made, and an emergency appendectomy performed. The appendix appeared normal at operation but was removed. Postoperatively, the patient continued to have fever, and on September 3 he became jaundiced. The icteric index rose to 51, and the blood urea nitrogen was reported as 45 mg. per 100 cc. Bile was present in the urine, and occasional granular casts were seen in the sediment on microscopical examination. Agglutinations for *L. icterohaemorrhagiae* were reported as 1:30 but rose to 1:3000 5 days later. Conjunctival hemorrhages appeared, and the patient's general condition grew worse for a few days. The patient was treated symptomatically with blood transfusions and dextrose infusions. Subsequently, the fever subsided, the jaundice cleared, and the patient was able to leave the hospital on September 11.

This patient was examined in routine fashion, and the emergency appendectomy was performed on the basis of the pain in the right side and the elevated white-cell count. There were several factors, however, that might have aroused the suspicions of the examiners. The cough at the onset of the illness, the absence of more signs of peritoneal irritation in the presence of an apparent acute appendicitis of three days' duration and the presence of albumin and cells in the urine were suggestive of a condition other than appendicitis. The difficulty in diagnosis was caused by the fact that jaundice did not appear early, which is true of most cases of Weil's disease.

Since the disease can readily be mistaken for an acute abdominal condition requiring surgery, the clinical aspects should be kept in mind so that it may be suspected early and prompt action taken to establish the diagnosis.

* * *

In 1886 Weil² first published his classic description of a specific infectious disease that has since been known as Weil's disease. In his report of 4 cases he was able to describe the condition in detail and to differentiate it from other types of acute

jaundice. The illness of his patients was characterized by severe chills, marked prostration, jaundice associated with hepatolienal enlargement, a hemorrhagic tendency and signs of renal failure.

Weil's observations stimulated others to look for this disease, resulting in a marked increase in the number of cases reported in foreign countries. It was not until 1922, however, that Wadsworth⁴ published the first account of a proved case of Weil's disease in the United States. From 1922 to 1941 Ashe, Pratt-Thomas and Kumpe⁵ were able to collect a total of only 67 reported cases in this country.

Epidemiology

In 1916 Inada⁶ found that the etiologic agent was a spirochete that was later classified and named *L. icterohaemorrhagiae* by Noguchi.⁷ The usual vector is the adult gray rat, and the rat population serves as a main reservoir for the spirochetes. The majority of cases occur as a result of contamination of the skin by the urinary excretion of infected rats. The organisms can live in a warm damp environment for days and may produce the disease in man by penetration through the nasal mucous membrane,⁸ the conjunctivas⁹ or abrasions of the skin.¹⁰ The disease is an occupational hazard to miners, sewer workers, fish cleaners and tunnel diggers. Rat elimination is the logical method for the control of the disease. Individual protection by avoidance of water or food likely to be contaminated by the excreta of rats should be practiced. The control problem is understandably difficult, and in New York Weil's disease is now recognized as a compensable disease in fish handlers.

Incidence

Weil's disease has been reported to be rare in children. The youngest patient in this series was thirteen years of age. Twenty of the patients were males, and 4 were females — a ratio of 5:1, as compared to that of 9:1 generally reported in this country. Davidson¹¹ has demonstrated that the difference in incidence between the sexes is purely occupational.

The reported seasonal incidence during the summer months is adequately illustrated in this series. Most of the cases occurred between April and October, 50 per cent of patients entering the hospital during August and September.

Clinical Features

The incubation period in these cases could not be determined, although it has been reported to average about ten days, with a range of four to nineteen days. The clinical course of the illness may be divided arbitrarily into three stages.

The first or septicemic stage usually lasts from two to five days and is characterized by the presence of spirochetes in the blood stream. The patient complains of an acute onset of nausea and vomiting,

myalgia, prostration, fever and chills. The bradycardia occasionally described was not found in any of the cases reviewed, the pulse rate varying from 110 to 150 per minute. The skin is hot and dry, and petechial hemorrhages may be found anywhere in the body. Abdominal pain is frequently present, although the abdomen is usually found to be soft and scaphoid. Tenderness may be elicited in the right upper quadrant, but there is no evidence of peritoneal irritation. Careful palpation reveals that the tenderness is frequently located in the abdominal wall itself and is probably caused by pathologic changes in the muscles.

The second or toxic stage is ushered in with the onset of jaundice. All but 1 patient in this series became icteric, although world statistics indicate that only half the patients with Weil's disease develop jaundice. Patients without jaundice do not have a second stage but proceed directly into the third or convalescent period.

Jaundice develops most frequently between the fourth and eighth days and is rarely accompanied by pruritus. Evidence of renal damage is also found at about that time. The patient appears extremely ill and may become stuporous, with occasional progression into coma or delirium. The temperature drops from the level of 104° to 106°F seen in the first stages to 100°F or even to normal. Signs of bronchopneumonia, with blood-streaked sputum, may be found. The liver becomes enlarged and tender. In 4 cases of this series the spleen was enlarged, although it has been stated by Ashe, Pratt-Thomas and Kump⁶ that the spleen is usually not palpable.

The convalescent stage is reached after the second week in patients who do not succumb. Kidney and liver function improve slowly after that time, the jaundice recedes, and the fever, which may have persisted into the second stage, subsides. During that period the patient complains only of weakness. Convalescence is complete as a rule in about four to six weeks.

All the patients with Weil's disease whose cases are reviewed were acutely ill on admission to the hospital and had one or more of the manifestations presented in Table 1. The onset of the disease was sudden in 18 cases, and 12 patients remembered the exact hour at which they had become ill.

The laboratory data found in this group of patients were in agreement with those described in the literature. In most cases the white-cell count ranged between 9500 and 24,000. One patient was found to have a leukemic level of 35,000, with a marked shift to the left. The urinary findings in these cases reflected the kidney damage that is present to some degree in all cases of Weil's disease. Albumin, red cells, a lowered specific gravity and a lowered phenolsulfonephthalein excretion were found in practically all cases. The blood urea nitrogen was above 100 mg per 100 cc in 10 patients, and in 1 it was 150 mg. The icteric index rose to

300 in 1 case, the average, however, ranged around 76. Cephalin-flocculation, hippuric acid and galactose-tolerance tests, when done, showed evidence of liver damage.

The agglutination titer for *L. icterohaemorrhagiae* was 1:300 or above in the 23 cases reviewed. Tests below 1:300 were not considered diagnostic of Weil's disease. Rising titers occurred in 17 patients and were of value in establishing the diagnosis when there was doubt regarding the etiology of the disease.

Spirochetes were seen on dark-field preparation in only 1 case. The neutral urine or the blood of 4

TABLE 1 Symptoms and Signs in Weil's Disease

SYMPTOMS AND SIGNS	NO. OF CASES
Fever	23
Headache	17
Muscular aches	17

Gingival hemorrhage	3
Epistaxis	2

patients when inoculated into guinea pigs produced findings characteristic of Weil's disease.

Diagnosis

Various provisional diagnoses were made either on admission or after a brief clinical survey before the diagnosis could be confirmed. Weil's disease was considered the most reasonable possibility in 8 cases, acute catarrhal jaundice in 8 cases, acute cholecystitis in 3 cases, bronchopneumonia in 2 cases, appendicitis in 1 case, and typhoid fever in 1 case. A high index of suspicion is evident from the fact that fully 33 per cent of patients were admitted with a tentative diagnosis of Weil's disease, requiring only confirmation by laboratory procedures.

A definitive diagnosis can be made in the first week of the disease by examination of the blood under dark-field illumination or intraperitoneal injection of 5 cc. of the patient's blood into a young, preferably pure-white, guinea pig weighing 175 gm or less. In the presence of the disease the young pigs become jaundiced and die in from ten to fourteen days. The spirochetes can then be found in the peritoneal fluid of the animal and in various organs.

On dark-field examination the organism appears as an actively motile spirochete from 8 to 15 microns in length and approximately 0.5 micron in width. It is tightly coiled and usually appears as a series

of brightly refractile spots alternately interspersed with nonrefractile areas of the same size. *L. ictero-haemorrhagiae* differs from *Treponema pallidum* in that it is more tightly coiled and has a sharp hook at one or both ends, which gives the organism an "S" or "C" shape. Careful study may be necessary to differentiate it from the numerous fibrin particles, which exhibit Brownian movement. Incubation at 27°C frequently increases the number of organisms in the specimen and aids in their demonstration. Examination of the urine is often of value during the second week, when the organisms are frequently present. Injection of the centrifuged sediment from 60 to 80 cc of fresh neutral urine diluted with 5 to 10 cc of physiologic saline solution into the peritoneum of a young guinea pig usually causes the death of the animal at the end of two weeks. Spirochetes can then be seen in the various organs by means of the Levaditi or Giemsa stain.

At about the end of the second week of the illness, antibodies appear in the patient's serum and agglutination tests may be performed. These tests are ordinarily of no value before the ninth day. Strongly false-positive reactions do not occur, and a negative agglutination test after the thirteenth day of illness rules out Weil's disease. High titers may persist for long periods.

Pathology

Post-mortem examination was performed on 2 patients in this series, and pathologic changes were noted primarily in the lungs, kidneys and liver. The lungs showed patchy areas of bronchopneumonia. The kidneys revealed interstitial infiltrations of round cells. The glomeruli were not remarkable but showed some enlargement of the capsular spaces. The tubules were dilated and filled with small amounts of amorphous pink-staining material. The tubular epithelium was swollen and granular. In 1 case Levaditi stains revealed numerous spirochetes within the tubules and in the surrounding stroma. The liver on microscopical examination showed considerable disorganization in the arrangement of the liver cells, which, instead of appearing in continuous cords, occurred in groups of two or three cells. Moderate vacuolization and swelling of the cells were noted. There was no evidence of intrahepatic block. Levaditi stains did not disclose spirochetes in either case.

These findings are in agreement with those described in the literature.^{6, 8, 12} Lesions in capillaries and skeletal muscles have been reported frequently. Capillary damage is manifested by numerous small hemorrhages, which can be found almost anywhere in the body, or by severe hemorrhage from any epithelial lined surface that can give rise to symptoms such as melena, hematuria, epistaxis and hemoptysis.

The changes in the muscles have been described as follows by Jeghers et al.⁸

There is vacuolization, swelling, loss of cross-striations, hyalinization, infiltration with histiocytes, polymorphonuclear leukocytes and plasma cells, breaking up the substance of the fibers into larger, round lumps of hyaline material, and reabsorption and proliferation of the nuclei of the sarcolemma.

The mechanism of the jaundice in Weil's disease has not been established. Ashe and his associates¹ state that the jaundice is probably due in large part to a true hepatitis. Increased hemolysis or intrahepatic obstruction has also been described by others as a factor in the production of jaundice in Weil's disease.¹³

Treatment

Arsenical drugs have no effect on the spirochetes and are dangerous in the presence of liver and kidney damage. Antimony compounds and sulfonamide drugs are also of no benefit.

Success has been reported in a few cases by treatment with sodium bismuth tartrate.

The therapy of choice at present is the use of penicillin in large dosage and of immune serum. The latter has been used in foreign countries with considerable success but has only recently become available in this country. Up to the present, transfusions of convalescent plasma or blood have been used. Four of the cases reviewed in this series were treated by the latter method and showed a marked response. The rest of the patients were treated by general supportive measures. Penicillin was not available for use in any case.

Mortality

There were 2 fatal cases in this group of 23 patients, a mortality of 8.7 per cent. Ashe, Pratt-Thomas and Kump⁶ found that the mortality in this country averaged 30 per cent. It is entirely possible that a number of patients in Charity Hospital of Louisiana died in the early stages of the disease before the diagnosis had been suspected, which may account for the relatively low mortality figure in this group.

SUMMARY

Two cases of early Weil's disease subjected to surgical exploration are reviewed in detail.

The clinical features of 21 additional cases are discussed.

Acute surgical abdominal disease and extrahepatic biliary obstruction can both be simulated by Weil's disease, which must therefore be considered in the differential diagnosis.

CARCINOMA OF THE BREAST

End-Results Massachusetts General Hospital 1933-1935

GRANTLEY W. TAYLOR, M.D.,* AND RICHARD H. WALLACE, M.D.†

BOSTON

THE present communication is the eighth in a series of reports from the Massachusetts General Hospital dealing with the results following operation for carcinoma of the breast.¹⁻⁷ There were 382 cases of carcinoma of the breast during the three-year period, 1933-1935, of which 328 were primary cases and 54 had received earlier treatment elsewhere. Of the former, 92 were inoperable when first seen, and 236 (72 per cent) were submitted to radical operation. Two cases that were untraced are regarded as failures, and 14 cases in which the patients died of intercurrent disease within five years are considered inconclusive. There were 5 postoperative deaths (2 per cent). Although historical data are incomplete, it seems probable that poor initial medical advice accounted for an advanced stage of the disease and consequent failure of cure in 19 patients. In 20 patients the original description of the lesion, with extensive matted axillary involvement, suggested that the operation was ill advised. These patients all succumbed to prompt recurrence, in 17 cases within a year of operation, although all received postoperative x-ray therapy.

In the present series, 40 per cent of patients reported for treatment within two months of the onset of the disease, whereas in 35 per cent the delay was more than six months. In the previous series of cases reported, only 31 per cent delayed over six months after onset. It should also be noted that the operability rate was 80 per cent in the previous series, compared to 72 per cent in the present group. Thus, it cannot be shown that propaganda has succeeded in shortening the time between the first symptom and operation, nor has

it caused patients to report in a stage more favorable for cure. On the other hand, the disease was limited to the breast without axillary metastases in 40 per cent of cases, in contrast to 37 per cent in the previous group. This fact, in conjunction with the lessened operability percentage, suggests that criteria of operability have been sharpened. There is still room for improvement in this respect, however, as shown by the 20 cases referred to above in which operation was ill advised.

Preoperative evaluation of axillary lymph-node involvement was erroneous in 19 per cent, generally in the direction of failure to detect involved nodes. This error is considerably less than that in previous series but emphasizes the inaccuracy of clinical appraisal of the extent of disease.

A hundred and twelve patients (50.4 per cent) were living without evidence of disease from five to eight years after operation. Of the cases without axillary involvement, 75.5 per cent were without recurrence after five or more years, whereas of those with axillary involvement the percentage was 33.3. It should be noted that in the latter group are included the 20 cases referred to above. If operation had been withheld from these cases, cures in the cases with axillary involvement would have been 39 per cent, and the operability rate for the entire group would have been 66 per cent. Although axillary involvement is thus obviously of great significance in the prognosis, it should be noted that when only one or two nodes prove to be involved the prognosis is comparable to that in cases without involvement. Specific notation of involvement of only one or two nodes was made in 15 cases, of which 12 (80 per cent) were in the "cured group." It is primarily in the cases with extensive or numerous axillary metastases that the prognosis is poor.

When the patients are divided into three age groups, it is evident that the prognosis is poorest in

†Assistant in surgery Harvard Medical School, associate visiting surgeon Massachusetts General Hospital, visiting surgeon Poodville State Cancer Hospital.

those younger than forty and most favorable in those over sixty years. The poorer prognosis for the younger group is probably due to the fact that this group presents a greater number of cases with higher grades of malignancy and with axillary metastases already established at the time of operation.

The cases of short duration show a definitely greater curability rate than those of longer duration. It should be observed that the lesions of a high grade of malignancy that are operable are usually of short duration. Hence, the group of short duration always contains a disproportionately large number of extremely malignant lesions, in which the prognosis is poor. The cures in such lesions are predominantly in the group of short duration and it is only in this group that a considerable number with this type of lesion are cured even when the nodes are involved.

The gross characteristics of the primary carcinoma, especially its size, are significant in the prognosis. Thus, five-year survivals were obtained in 89 per cent of cases with lesions less than 2 cm in greatest diameter, in contrast to 18 per cent if the lesions were greater than 4 cm in diameter. The same disparity obtains when cases with or without lymph-node involvement are contrasted. The larger the primary lesion, the greater the incidence of involvement.

The lesions were grouped into three grades of malignancy, according to Greenough's criteria. There were only 11 cases in the lowest grade. None of these presented axillary lymph-node involvement, and cure resulted in all cases. Axillary nodes were involved in 60 per cent of cases with Grade II lesions, and in 65 per cent of the lesions of highest grade. Cure was achieved in 59 per cent of cases with Grade II lesions, including 86 per cent of those without and 40 per cent of those with lymph-node involvement. Cure was obtained in 38 per cent of cases with Grade III lesions, including 57 per cent of those without and 27 per cent of those with nodes. It is obvious that the cases of high malignancy have a poorer prognosis when cases of comparable extent are considered, and it is also evident that a high proportion of these patients present axillary metastases when first seen. Another finding of significance is that local recurrence took place in 18 per cent of cases with Grade III lesions, in contrast to 7.6 per cent of those with Grade II lesions.

Biopsy and immediate pathological examination were performed in 116 cases. Fifty-five of these patients proved to have axillary involvement already present, which suggests that biopsy was resorted to in many cases when the diagnosis was probably clinically obvious. Although the over-all results in the biopsied group show 57 per cent five-year survivals, this favorable showing is doubtless due to the inclusion of a large proportion of the early and

doubtful cases. That the procedure is not entirely free from hazard is shown in the fact that recurrence in the operative field occurred in 15 per cent of the biopsied group, in contrast to 7.5 per cent in the cases not submitted to biopsy.

Recurrences in the operative field may constitute a reflection on the care with which cases are selected for operation and on the operative technic. There was such recurrence in 11 per cent of the present group. As noted above the rate was highest in cases with a high grade of malignancy and also in cases submitted to immediate pathological examination. It is also noteworthy that there is an increased likelihood of operative-field recurrence when the primary carcinoma is large and when axillary metastases are present. Although these findings are not conclusive, they suggest that the extent and character of the primary carcinoma have greater significance than the operative technic.

X-ray therapy has been used as the treatment of choice in inoperable cases and in the treatment of recurrences. Preoperative x-ray therapy has not been employed. Postoperative x-ray therapy was used in a certain number of cases in which the surgeon believed that he had left gross carcinoma after operation, and in some others in which clinical and pathological features augured a poor prognosis. It was not employed routinely in the present series, and it is not demonstrable that any benefit was obtained in the cases in which it was used prophylactically.

SUMMARY

This report is the eighth in a series of end-result studies of carcinoma of the breast treated at the Massachusetts General Hospital.

Survivals of five to eight years without recurrence were obtained in 75.5 per cent of cases without axillary lymph-node involvement, in 33.3 per cent of those with axillary metastases and in 50.4 per cent of the entire group submitted to radical operation.

Improvement in curability, as compared with that in previous series of cases, may have been due to better selection of cases suitable for operation, as well as to improved operative technic. Benefits due to shortening of the preoperative duration as a result of educational campaigns were not conspicuous in this series. The occasional employment of postoperative prophylactic radiation does not appear to improve the prognosis.

The presence or absence of axillary lymph-node metastases is of marked significance in the prognosis. Other important factors are the size and duration of the primary lesion, the grade of malignancy and the age of the patient. These factors not only affect the prognosis but also have a bearing on the incidence of operative-field recurrence.

PLASMA-VOLUME DETERMINATIONS IN RHEUMATIC SUBJECTS DURING ORAL SALICYLATE THERAPY*

Report of a Case with Severe Hemorrhage

CHARLES L. YORK, M.D.,† AND WILLIAM J. H. FISCHER, JR., M.D.‡

PROVIDENCE, RHODE ISLAND

COBURN'S¹ report advocating large doses of salicylates in rheumatic fever aroused widespread interest in the problem of salicylate intoxication. The milder symptoms of nausea, vomiting, tinnitus, deafness and vertigo are considered to be of minor significance. The origin of these symptoms and the action of sodium bicarbonate in alleviating them have been discussed by Smull and her associates² and Caravati and Cosgrove.³ The more serious toxic complications, including death, delirium, dyspnea, acidosis, hypoprothrombinemia and hemorrhage have been investigated by Ryder et al.,⁴ Manchester,⁵ Owen and Bradford⁶ and Jager and Alway.⁷ The last investigators suggested the possibility of an increased plasma volume during intensive salicylate therapy because of changes noted in the hematocrit and plasma proteins and by determination of the plasma volume by the dye method in some cases.

Accordingly, 7 rheumatic patients receiving large oral doses of sodium salicylate were studied for changes in the plasma volume.

MATERIALS AND METHODS

Of the patients studied 6 had rheumatic fever, and 1 had rheumatoid arthritis. The plasma volume, hematocrit and plasma protein concentration, prothrombin activity and salicylate concentration were determined on admission. The patients were then given sodium salicylate orally without sodium bicarbonate in a dosage such that plasma salicylate concentrations of not less than 35 mg per 100 cc were expected.

Plasma volumes were determined by the ten-minute-sample method of Gregersen⁸ and Noble and Gregersen,⁹ as modified to the use of the Cenco

photometer. A calibrated syringe was used for the injection of the dye T-1824.[§] Duplicate venous hematocrits determined in Wintrobe tubes and plasma protein determinations by the method of Bowman¹⁰ were done on the control and dye samples. The prothrombin time was determined by a modification of the Quick¹¹ method using thromboplastin prepared from the human brain. The prothrombin activity as a percentage was obtained by comparison with diluted normal human plasmas. Plasma salicylate concentrations were determined by a modification of the method described by Coburn.¹

The plasma volume, hematocrit and plasma protein concentration, prothrombin activity and salicylate concentration, which were determined at frequent intervals during therapy, are presented, with other relevant data, in Table 1.

RESULTS

An increase in the plasma volume was noted within ten days after the beginning of oral salicylate therapy in 5 of the patients in this study. Changes in the plasma volume are better expressed as percentage change, in that the actual volume varies with the weight and size of the patient. The increases noted were 38 per cent (1450 cc) in Case 1, 65 per cent (210 cc) in Case 3, 16 per cent (550 cc) in Case 5, 14 per cent (275 cc) in Case 6 and 11 per cent (340 cc) in Case 7. A decrease in plasma volume occurred in 2 cases, being 96 per cent (240 cc) in Case 2 and 40 per cent (80 cc) in Case 4.

In 8 convalescent patients with no evidence of cardiovascular disease, a series of thirty-four control determinations of plasma volume by the method used in this study showed variations from +4.3 to -6.9 per cent.

*From the Department of Medicine, Rhode Island Hospital and the Department of Medical Sciences, Brown University Medical Department. †Senior resident in medicine, Rhode Island Hospital. ‡Fellow in Medical Sciences, Brown University Medical Department.

§Kli-dip supplied by the Warner Institute of Therapeutic Research, New York City.

The greatest increases in plasma volumes occurred in patients with pre-existing valvular disease who were experiencing salicylate toxicity. Cases 1 and 5 showed evidences of salicylate intoxication by anxiety, severe tinnitus, gross tremor, acidosis (acetonuria and lowered carbon dioxide combining power), lowered prothrombin activity and pul-

owing to poor co-operation on the part of the patient necessitating lower dosages. In the latter there was blood loss, and twenty-four hours after the second plasma-volume determination, clinical shock was evident.

After prolonged sodium salicylate therapy 6 patients showed plasma volumes that were increased

*Functional capacity based on criteria outlined by the Criteria Committee of the New York Heart Association.¹¹

monary congestion (basal rales) at the time the second plasma volume was determined. In Case 6 the same symptoms and signs were demonstrated, but the carbon dioxide combining power was not measured. One patient (Case 3) never had more than mild symptoms of intoxication.

Decreased plasma volumes occurred in Cases 2 and 4. In the former the salicylate concentration in the blood never exceeded 22 mg per 100 cc,

from the initial values. The average increase was 9 per cent. One patient (Case 3), who was treated in an original monocyclic attack of acute rheumatic fever and who showed an increase of 6.5 per cent in plasma volume after a week of intensive oral salicylate therapy, had a return of the plasma volume to the original level while continuing the salicylate. When rechecked two weeks after the last dose of drug a plasma volume 6 per cent less than that on

admission was found. In the remaining 5 cases, once the increase had occurred, the plasma volume remained at an elevated level even after all medication had been omitted, and only slowly returned toward the initial value.

From our data it is evident that the hematocrit and plasma protein determinations did not consistently reflect the changes in plasma volume as measured by the dye method.

Changes in the prothrombin activity in 6 patients followed a rather irregular pattern. In the main, however, whenever a plasma salicylate concentration of over 35 mg per 100 cc was present, there was a definite and persistent depression of the prothrombin activity. Hemorrhagic episodes were not observed in any case except in Case 2. One patient (Case 1) had a prothrombin activity of 0 on admission, but it could not be established whether or not salicylates had been administered before admission. Another patient (Case 2), whose prothrombin activity had progressively decreased while he was receiving massive doses of salicylate therapy orally, developed severe intoxication and hemorrhage. This case is reported in detail below.

CASE REPORT

D V., a 13-year-old boy, was admitted to the hospital with a history of repeated episodes of nasal bleeding and painful swelling of the joints of brief duration. He had had rheumatic fever 3 years previously, when he had been treated with prolonged bed rest; he had subsequently been limited in school athletics because of a heart murmur.

Physical examination revealed a well developed and well nourished boy, who appeared ill and obviously favored the left knee. There was mild injection of the pharynx. The lungs were clear. The apical impulse was heaving and palpable in the fifth left interspace in the midclavicular line. The left border of cardiac dullness fell at the same point. The rhythm was regular, and the rate rapid. There was a soft, blowing systolic murmur at the apex and harsh systolic and blowing diastolic murmurs at the base and along the left sternal border. The abdomen was soft and nontender, and the liver and spleen were not palpable. The left knee and, to a lesser degree, both ankles were red, hot, tender and swollen.

The temperature was 102 F and the pulse 120. The blood pressure was 120/60.

The patient had previously received salicylates before admission since the blood salicylate concentration was 15 mg per 100 cc and the prothrombin activity was 60 per cent. He was given 10 gm of sodium salicylate daily by mouth. A prompt clinical response occurred within 24 hours. This dosage was continued for 4 days, when nausea and anorexia, anxiety, a gross tremor, flushing and sweating, an increased respiratory rate without dyspnea and a few fine rales at the right base first appeared. The carbon dioxide combining power was 40 vol. per cent, and a urinalysis was negative except for a + test for acetone. The plasma salicylate concentration was 64 mg per 100 cc and the prothrombin activity 12 per cent of normal.

On that day of treatment bleeding from the nose was first noted but did not appear to be severe, since the amount of blood was small and examinations of the posterior pharynx did not suggest that any great amount of blood was being lost by this route. During the afternoon the patient vomited once, and there was no gross blood in the vomit. Vomiting recurred on the following morning. Its appearance suggesting old blood to the nurse, but the specimen was discarded. Throughout the 5th day there was intermittent nasal bleeding and 6 gm of sodium salicylate was given. A plasma-volume determination was 9.6 per cent (240 cc.) less than that on admission. The nasal bleeding continued during the night. On the following day the patient appeared listless and

pale and complained of nausea and malaise. Salicylates were omitted. During the early evening the patient fainted in bed. He immediately regained consciousness, and examination revealed no evidence of nasal bleeding at that time. The blood pressure was 110/45. Shortly thereafter the patient vomited 600 cc of bright red, loosely clotted blood. An hour later a similar amount was vomited and the blood pressure was 94/40. The prothrombin activity at that time was reported as less than 10 per cent. The patient was immediately given molar sodium lactate and 64 mg of menadione bisulfite intravenously, as well as 500 cc of fresh whole blood. A third vomiting of 500 cc of bright red blood occurred before transfusion. Two hours after the transfusion the blood pressure was 120/40, no further evidence of bleeding occurred. Further transfusions were given on the following 2 days. On the 3rd day after the last dose of salicylate, the plasma salicylate concentration was 0 and the prothrombin activity was 60 per cent of normal. The patient was asymptomatic at that time. Twenty-four hours later the temperature reached 103 F, and he complained of abdominal pain, dryness of the throat and a desire to cough. The chest was clear but the abdomen was diffusely tender with rebound tenderness but no localizing signs. Sodium salicylate was resumed with a daily dose of 4 gm orally, and the administration of 25,000 units of penicillin every 3 hours prophylactically was begun. A prompt amelioration of symptoms resulted. Penicillin was continued for 8 days and the salicylates were increased to 5 gm daily. The prothrombin activity remained within normal limits. Thereafter, convalescence was uneventful. A plasma volume determined 16 days after the hematocrits and transfusions was increased 8.5 per cent (450 cc.) over the initial volume. The plasma salicylate at that time was 17 mg per 100 cc.

DISCUSSION

From this study of 7 patients who received oral sodium salicylate therapy it is evident that the plasma volume tends to increase at some point during the course of treatment. A possible explanation for this may be found in the study of Lyons, Jacobson and Avery,¹³ who demonstrated a significant increase in the plasma volume in 14 normal subjects who received large amounts of sodium chloride or sodium bicarbonate by mouth. It is our hypothesis that with large doses of sodium salicylate enough sodium may be ingested to result in a measurable increase in the plasma volume. In patients receiving both sodium salicylate and sodium bicarbonate such an effect would be even more reasonable.

In Case 1 a prompt increase in the plasma volume of 38 per cent was noted. This increase was coincidental not only with signs of salicylate toxicity but also with clinical evidence of increasing heart failure. This patient, with pre-existing aortic and mitral valvular disease and a recurrence of acute rheumatic fever, was admitted in mild chronic congestive failure. He showed an initial high plasma volume. This is consistent with the reports of Gibson and Evans,¹⁴ Seymour et al.¹⁵ and Warren and Stead.¹⁶ In such cases the addition of more sodium ions through the medium of sodium salicylate therapy may have been the basis for a further increase in plasma volume and a coincident increase in heart failure.

SUMMARY

Definite increases in plasma volume occurred in 6 of 7 patients studied during oral sodium salicylate therapy.

The degree of prior valvular damage, together with the acute disease and the added sodium ions of the drug, appear to be the factors responsible for the increase in plasma volume

When plasma salicylate concentrations were maintained in the range of 35 mg per 100 cc, an associated depression of prothrombin activity was found

One case is presented in detail because of the occurrence of a severe hemorrhage, associated with a marked hypoprothrombinemia

HEMATOLOGY (Concluded)*

WILLIAM DAMESHEK, M.D.†

BOSTON

HEMORRHAGIC DISEASES

As previously stated the hemorrhagic diseases may be classified as those due to a defect, usually a reduction, in the blood platelets, to a defect in the coagulation factors of the blood and to a disturbance of the capillaries⁹¹

Thrombocytopenic Disorders

Qualitative abnormalities of the platelets undoubtedly exist, but they are exceedingly rare as compared with quantitative changes. Marked reductions in blood platelets (thrombocytopenia) occur in a number of conditions and may be due to bone-marrow disease, such as hypoplasia, aplasia, leukemia or other infiltration, deficiency of liver-extract principle (pernicious anemia), iron or certain components of the vitamin B complex including folic acid, to the hypersplenism of splenomegaly that is caused by cirrhosis of the liver, chronic infectious splenomegaly, disorders of lipid cellular

metabolism and other conditions, allergic reactions to drugs and foods; various conditions, usually infectious diseases but with the bone-marrow picture as seen in the idiopathic group mentioned below, and unknown disorders usually associated with the "hypersplenism" of an abnormal spleen and generally requiring removal (idiopathic thrombocytopenia)

In thrombocytopenia due to actual disease of the bone marrow, whether hypoplasia, aplasia, leukemia or neoplastic infiltration, the sternal-puncture aspiration of the marrow shows great diminution or complete lack of megakaryocytes. In idiopathic thrombocytopenia megakaryocytes are numerous. Thus, a simple puncture-aspiration biopsy of the sternal marrow is of great value in differentiating the two types of disturbance.

Thrombocytopenic purpura as a complication of an acute infectious or exanthematous disease is fairly common. This is particularly true of children. Kaufman⁹² reports the cases of 2 children who developed thrombocytopenic purpura after scarlet fever. The second case showed 8 per cent eosinophils in the blood. Unfortunately, sternal-marrow examinations were not done. Methionine and foods high

in this amino acid were used for treatment with prompt cessation or diminution in the hemorrhagic tendency. Further trial with this therapeutic method is desirable. Two cases of German measles complicated by thrombocytopenic purpura are reported by Warren, Rogliand and Potsabay.⁴² Uneventful recovery ensued in both, as it almost always does in cases associated with an acute infection. In a case of infectious lymphadenosis (mononucleosis) presented by Dameshek and Grassi,⁴³ however, the thrombocytopenia and bleeding were so marked that splenectomy had to be resorted to and was followed by dramatic recovery. It was thought that the large spleen that was present was contributing to the development of marked "hypersplenism" and thus to the thrombocytopenia. Thrombocytopenia occurring in the course of malaria is reported by Schrager and Kean.⁴⁴ This is extraordinarily rare, occurring perhaps once in 10,000 cases of the disease.

Boeck's sarcoid with thrombocytopenic purpura is reported by Enzer⁴⁵ and by Nordland et al.⁴⁷ In Enzer's case there was generalized sarcoidosis with splenomegaly and pancytopenia. Splenectomy was followed by uncontrollable hemorrhage, which led to death. On the other hand, I have seen cases of Boeck's sarcoid of the spleen in which splenectomy led to a complete recovery in the platelet level and cessation of bleeding. Nordland and his associates⁴⁷ observed a similar case in which what appeared to be typical fulminating idiopathic thrombocytopenic purpura developed during the fifth month of pregnancy. Splenomegaly was present, however, and was difficult to explain, since in the idiopathic disease the spleen is hardly ever enlarged. The spleen was removed and showed Boeck's sarcoid, and the patient made an uneventful recovery. The author discusses 13 cases of idiopathic thrombocytopenic purpura, 7 with splenectomy during pregnancy. Patterson⁴⁸ reports a case of idiopathic purpura occurring during pregnancy in a twenty-two-year-old primipara with a strong family history of hemorrhagic disease. Bleeding manifestations began during the fifth month of pregnancy, and postpartum bleeding was excessive. The newborn infant developed purpura and bleeding in the stools and showed a platelet level of 18,000. Both the mother and the infant subsequently recovered. This case is worthy of comment for several reasons: the occurrence of thrombocytopenic purpura in the infant of a thrombocytopenic mother indicates the possibility of a circulating antiplatelet growth factor, which is consistent with the conception, expressed below, of a splenic factor that enters the blood stream and causes inhibition of megakaryocytes, and the question is open whether conservative treatment was justified in this case even though it worked out happily, since the mother might have bled uncontrollably at delivery. Had splenectomy been performed at the fifth month, the baby would not

have developed thrombocytopenia, and the maternal bleeding would have been minimal at delivery.

Some cases of the hypersplenism caused by splenomegaly continue to be reported as idiopathic thrombocytopenic purpura. Splenomegaly is often associated with leukopenia, neutropenia, thrombocytopenia and anemia.⁴¹ There is either pancytopenia or a selective cytopenia or group of cytopenias. The splenomegaly may be due, as noted above, to Boeck's sarcoid, chronic infections of the spleen, cirrhosis of the liver, splenic-vein thrombosis, Gaucher's disease or unknown causes. Splenectomy usually brings the blood picture back to normal whatever the underlying condition. Suchacki and Glass⁴⁹ report the case of a Nigerian Negro with a large spleen in whom marked hemorrhagic manifestations (diagnosed as idiopathic thrombocytopenic purpura) were present. The blood showed pancytopenia. Splenectomy was followed by a dramatic response.

Dameshek and Miller¹⁰⁰ discuss the sternal-marrow findings with particular reference to the megakaryocytes in idiopathic thrombocytopenic purpura, which they regard as a form of hypersplenism. The blood in this condition is characterized by an extreme reduction in platelets. Paradoxically, however, the platelet precursors in the marrow—that is, the megakaryocytes—are increased. Careful histologic study of the megakaryocytes demonstrated a greatly diminished platelet production. After splenectomy platelet production became extraordinarily marked, indicating that before splenectomy something had been inhibiting platelet production from megakaryocytes. Since splenectomy resulted in correction of this defect, the spleen was suspected of being the site of an abnormal material or an abnormal amount of normal material causing megakaryocytic inhibition. The disorder was thus thought to be a form of hypersplenism with enlargement of the spleen. The diagnostic value of the sternal-puncture test in the differentiation of idiopathic and other forms of purpura is discussed.

Schwartz⁵¹ reports the bone-marrow findings in idiopathic thrombocytopenic purpura, with particular reference to the concentration of eosinophils and their diagnostic and prognostic significance. He observed that when more than 50 eosinophils were found per 1000 granulocytes the patient usually made a spontaneous recovery without splenectomy. These cases were thought to be of allergic nature. There can be no question that an allergic reaction—whether to an infection, drug or food—results in a megakaryocytic reaction, with a reduction in platelets. Schwartz's contention that the finding of marrow eosinophils is definitely indicative of such a reaction cannot yet be definitely proved.

Aggeler, Howard and Lucia⁵² discuss their data on platelet counts as related to bleeding time, coagulation time, capillary fragility and degree of

clot retraction in 64 normal subjects and in 404 patients suffering from various diseases. The counts are of distinct value if done by the same person day after day. Parenthetically, it may be said that platelet counts performed only occasionally are best not done at all, since they are subject to great inaccuracy. Estimation of the number of platelets on a well spread cover-slip smear is much better than the occasionally performed platelet count. Aggeler et al found a statistically significant relation between the platelet count, the bleeding time and the clot retraction. In the stage of recovery from idiopathic thrombocytopenic purpura there may be some dissociation between these factors.

A peculiar type of thrombopenic purpura associated with hemolytic anemia and generalized platelet thrombosis is described by Trobaugh and his associates¹⁰³. Death occurred two weeks after the onset of illness. At autopsy widespread platelet thrombi were present in small blood vessels throughout the body. About 15 similar cases have already been recorded. Graña^{104, 105} reports the experimental production of thrombopenic purpura in dogs and guinea pigs by the injection of heterophil antibody of the Forssman type. Not only was the platelet count depressed but also the capillary walls showed evidence of injury. This paper points to the possibility of an abnormal agglutinating mechanism in the pathogenesis of some cases of idiopathic thrombocytopenic purpura. Skelton and his co-workers¹⁰⁶ found that alpha tocopherol (vitamin E) prevented or cured the picture of experimental thrombocytopenic purpura of antiplatelet serum. This material was apparently used with beneficial results (although detailed statements are not made) in 5 cases of idiopathic thrombocytopenic purpura and in 5 cases of other types of purpura. This form of therapy requires further study.

A case of thrombocytopenic purpura due to potassium iodide administration is reported by Davis and Saunders¹⁰⁷. Discontinuance of the drug resulted in subsidence of the purpura, and experimental reproduction was achieved later by a single administration of 0.5 gm. The development of purpura during heat stroke was studied by Wright, Reppert and Cuttino¹⁰⁸. The hemorrhagic disturbance was apparently the end result of both thrombocytopenia and a decrease in prothrombin concentration of the blood, the latter being due probably to extensive hepatic damage. Bone-marrow smears revealed no abnormalities of the megakaryocytes.

Defects in Coagulation Factors

Hypoprothrombinemia The most frequent coagulation defect is that involving prothrombin. Quick^{109, 110} emphasizes repeatedly that his original methods for the preparation of thromboplastin and for performing the prothrombin test have been considerably modified, leading in many cases to

inaccurate results. Aggeler and his associates¹¹¹ present a critical analysis of the Quick test for prothrombin and conclude that the use of a single specimen of blood from one normal subject as a normal standard may lead to considerable error. To establish reliable normal standards, the blood of at least 5 normal subjects should be individually tested with the same specimen of thromboplastin, and the results averaged. It is suggested that a carefully prepared and stored dehydrated human brain is a more potent source of thromboplastin than the average rabbit brain.

The development of hypoprothrombinemia during salicylate therapy appears to be a definite phenomenon. Govan¹¹² reports his studies of 24 children receiving salicylates, mostly aspirin. In 6 cases an abnormal prolongation of the prothrombin time occurred. The most marked changes occurred between the second and fifth days of medication. Despite continuation of salicylates, the prothrombin time returned to normal values by the ninth day. Owen and Bradford¹¹³ studied 25 adults with rheumatic fever who received 10 gm of salicylates intravenously daily. The prothrombin levels fell to 10 to 59 per cent of normal within one to six weeks. Bleeding in the form of epistaxis or splinter hemorrhages occurred in 5 cases at the time of maximum prothrombin depression. Clausen and Jager¹¹⁴ attempted to correlate the degree of hypoprothrombinemia with plasma salicylate levels rather than with the total daily dose. A direct correlation was found in both human beings and animals between the height of the plasma salicylate level and the degree of hypoprothrombinemia. Significant reductions in the prothrombin level (to 40 per cent of normal) did not occur until plasma salicylate levels of at least 600 microgm per 100 cc were reached, varying doses of salicylates being required for this purpose.

Prolongation of the prothrombin time by quinine was reported by Pirk and Engelberg¹¹⁵. Quick¹¹⁶ studied this matter further and found no such prolongation. He also showed that the administration of vitamin K in large doses did not cause a hyperprothrombinemia. In this article Quick attempts to discredit further use of the term "hypoprothrombinemia."

A diminution in circulating prothrombin (increased prothrombin time, hypoprothrombinemia) occurs not only in obstructive jaundice and hepatitis but also in severe dietary inadequacy, in chronic diarrhea and in pregnancy. Rapoport and Dodd¹¹⁷ report 7 cases of hypoprothrombinemia in infants with prolonged diarrhea. The hemorrhagic manifestations and the prothrombin levels were adequately controlled by the parenteral administration of vitamin K.

Meyers and Poindexter¹¹⁸ studied the prothrombin levels in patients with both occlusive coronary disease and angina pectoris. Coronary occlusion

produced a definite shortening of the prothrombin time within twenty-four to seventy-two hours after the beginning of the attack and lasting for several weeks. This abnormality may be due to a release of excess thromboplastin from injured heart muscle and perhaps by disintegration of platelets in the mural thrombus.

Ogura et al.¹¹⁸ studied 27 cases of coronary occlusion by the Waugh-Ruddick test and demonstrated accelerated prothrombin time in 78 per cent of cases. This occurred beginning with the second or third day and continued until the seventeenth day. The technic of the Waugh-Ruddick test is described in the article. Cotlove and Vorzimer¹¹⁹ observed the prothrombin time in 76 cardiac patients and found that no alterations in this test occurred in either coronary occlusion or angina pectoris. (These contradictory findings have no particular bearing on the use of dicoumarol for the treatment of coronary thrombosis, as suggested by Wright and his associates.¹²⁰ Whether the use of dicoumarol represents good medical practice is not yet completely certain.)

Scherf and Schlachman¹²¹ studied the prothrombin time in 22 cardiac patients receiving methylxanthines such as aminophylline and theobromine and found a shortening of the prothrombin time. Whether these results have any definite significance is questionable, in view of the undoubted limitations of the present tests for prothrombin. An attempt to introduce a good deal more accuracy into the present tests for prothrombin has been made by Deutsch,¹²² who devised a photoelectric method for studying thrombin. This method deserves further investigation. Levy and Conroy¹²³ recorded the blood prothrombin (by the Smith bedside test) in patients receiving anesthesia. Ether anesthesia shortened the prothrombin time and therefore may be of some importance in the causation of post-operative thrombosis.

Hemophilia. Tocantins¹²⁴ reviews the various factors having to do not only with coagulation but also (which is quite as important) with preventing blood from clotting within the circulation. The coagulants are well known and include thromboplastin (cephalin), prothrombin and fibrinogen. The anticoagulant factors are less well known and may be listed as follows: an intact vascular endothelium, antithromboplastin, antithrombin and fibrinolysin. Blood clotting may be enhanced either by an increase in coagulation factors or by a decrease in anticoagulant factors. Tocantins believes that hemophilia is due to an excess of anticephalin (antithromboplastin) activity and not to a diminution in a thromboplastin-plasma material as maintained by the various workers at the Thorndike Memorial Laboratory of the Boston City Hospital. Lewis et al.¹²⁵ review their studies of the past decade in the physiopathology of hemophilia and conclude that the disease is due to a great deficiency in a

globulin fraction of the plasma, which may be called the "antihemophilic globulin." In this paper, allusion is also made to Tagnon's work on the presence in normal plasma of a proteolytic fibrinolytic enzyme, having as yet unidentified role in blood coagulation. Tagnon and his co-workers¹²⁶ contribute another article dealing with the fibrinolytic enzyme chiefly in hemorrhagic shock. Munro,¹²⁷ in common with Tocantins in this country and Pavlovsky in Buenos Aires, found an anticoagulant substance in the blood of a hemophilic patient. The anticoagulant was found not to be antiprothrombin, heparin or antithromboplastin but was a lipoprotein apparently identical with the anticoagulant described some years ago by other observers. Fantl and Nance¹²⁸ found a circulating anticoagulant in the blood of a woman with severe hemorrhagic disease and a greatly prolonged coagulation time. It was determined that the material was an antithromboplastin.

The treatment of hemophilia has measurably advanced but not yet to the goal of complete control. Thrombin or fibrin foam will control to a large extent minor local bleeding, such as that from the gums, dental sockets, nose and skin, and even major operations have been performed with the use of these materials.

Employment of the antihemophilic globulin derived from the plasma fractionation program of Harvard Medical School has demonstrated a striking effect on the bleeding of hemophilia when only 100 to 200 mg of the material is given intravenously. The daily use of this substance, however, is impractical. Van Creveld and Mastenbroek¹²⁹ present a preliminary report on a hemophilic patient in whom the administration of 24 cc. of a 2 per cent solution of this fraction promptly reduced the coagulation time to normal and maintained it so for forty-eight hours.

The extraordinarily rare afibrinogenemia, which is usually congenital, is considered by Pinniger and Prunty.¹³⁰ In a case of severe hemorrhagic disease in a girl, these observers found a greatly prolonged clotting time and an almost complete lack of fibrinogen. Transfusion of reconstituted dried plasma was effective in controlling the bleeding and improving the fibrinogen deficiency. Rocha e Silva and his associates¹³¹ demonstrated a great reduction in circulating fibrinogen in experimental shock produced by trypsin, peptone and ascari extracts.

Hemorrhagic Capillary Disorders

Undoubtedly, the most frequent of the hemorrhagic disorders are those due to abnormalities of the capillaries. These occur in infectious diseases, deficiency states, at times with endocrine disorders and congenitally or idiopathically. The "devil's pinches" in soft-skinned women are often the cause for alarm but in reality have little if any significance. Whether they have anything to do with an

excess of circulating estrogen is questionable. All the various hemorrhagic factors in these cases, including platelets, prothrombin, clotting and bleeding factors, are normal. In rheumatic fever and acute glomerulonephritis purpuric manifestations are not rare. The platelets are normal, but apparently there is a more or less generalized disorder of minute blood vessels with seepage into the skin. Jones and Moore¹³² discuss 3 such cases. Montgomery¹³³ found a definite increase in capillary fragility. No effect on the hemorrhagic disturbance or the capillary fragility was obtained with the use of vitamin P (derived from paprika).

A hemorrhagic disorder of mucous membranes with the formation of bullae and vesicles is reported by Foley¹³⁴ in a group of American and British prisoners of war confined to a Japanese prison camp. Crops of vesicles and hemorrhagic bullae developed on the buccal, palatal and tonsillar mucosa. No skin manifestations were present, and all the tests for hemorrhagic disturbance were negative. There was a quick response to the use of a high-protein, high-fat diet, but vitamins of various sorts were of no value. In occasional cases of hemorrhagic capillary disease one can make the diagnosis of Henoch-Schönlein purpura. In the Henoch type hemorrhagic manifestations are associated with intestinal disturbances, which may include abdominal pain, hematemesis and melena. Such a case is reported by Whitmore and Peterson¹³⁵. In the Schönlein type joint manifestations are present. Since purpura, joint manifestations and intestinal disturbance may all coexist the designation of Henoch-Schönlein purpura is justified.

A hereditary capillary defect is that known as hereditary hemorrhagic telangiectasia. Kushlan¹³⁶ reviews the historical and clinical aspects of the disorder and reports a case. The newly introduced material called rutin was used in a dosage of 40 mg daily by mouth. There was "prompt" cessation of epistaxis, of gum bleeding and, finally, of gastrointestinal bleeding. The patient had been maintained for several months on a daily dosage of 20 mg of rutin.

During the past year a number of articles dealing with rutin have appeared. This is a crystalline glucoside of quercetin derived from buckwheat leaves and flowers, tobacco leaf, rue herb and many other plants. Chemically, it is a derivative of flavone and related closely to hesperidin (vitamin P), citrin and ascorbic acid. It appears to have no toxic manifestations. Shanno¹³⁷ used the material in a variety of cases showing increased capillary fragility, and in all cases except those with thrombocytopenic purpura and allergic purpura there was a return to normal of the capillary fragility following the use of the drug. In a report to the Council on Pharmacy and Chemistry of the American Medical Association, Smith¹³⁸ takes this and other articles on rutin to task. The procedures for measuring

capillary fragility are crude, and there is no complete agreement among the workers in the field on the reliability of the methods. It is probable that before another year has passed, the results with rutin therapy will have been fully assessed.

A queer hemorrhagic disorder characterized by a prolonged bleeding time is that of pseudohemophilia. The tendency to unusually profuse and continued bleeding after minor trauma resembles the bleeding of hemophilia. In about half the cases a definite family history of profuse bleeding in both females and males is obtained, with transmission by either sex. In such a case reported by Perkins¹³⁹ there was uncontrollable bleeding after minor operative procedures, and the development of large ecchymoses with slight trauma. The history of bleeding could be traced through five generations, and there was transmission from father to son. In addition to the abnormal bleeding time, a failure of capillary retraction (as previously noted by MacFarlane) was observed by means of capillary microscopy. Estren, Sanchez Médal and Dameshek¹⁴⁰ review the subject of pseudohemophilia and their experiences with 11 cases. The literature, clinical and laboratory features, diagnosis and therapy, together with a critical review of methods for the study of hemorrhagic disorders, are presented. The disorder, which is by no means rare, appears to be due to a congenital or hereditary defect of capillary retractility. In some ways it is more difficult to treat than hemophilia itself, since transfusions of blood are ineffective.

CASE 33391

PRESENTATION OF CASE

A twenty-three-year-old man entered the hospital in shock.

About five years before admission the patient had several spells of unconsciousness, which at that time were thought to be petit-mal attacks. Systolic murmurs were noted at the base of the heart on several examinations thereafter. Four months prior to entry he began to experience throbbing frontal headaches, upper respiratory infection, with coryza, mild soreness of the throat and a cough productive of small amounts of sputum. At about the same time he began to have soreness of the left shoulder radiating down the arm for a short distance. Three weeks later there were several episodes of epistaxis, and he was given a sulfonamide for a week, during which time he had night sweats but no fever or chills. The soreness of the shoulder and other symptoms persisted, and he was admitted to another hospital one month after the onset of symptoms, or three months before admission to this hospital.

Examination at the other hospital revealed a pericardial friction rub but no valvular murmurs. An electrocardiogram showed flattening of the T segments in Lead 1, with inversion of the T waves in Leads 2 and 3. X-ray films of the chest revealed generalized enlargement of the heart, with thin arcuate calcifications overlying the left border. On admission the sedimentation rate was 65 mm per hour, two and a half weeks later it was 35 mm. A blood culture was negative. The nonprotein nitrogen was 53 mg per 100 cc. The Mosenthal test was normal. In the hospital the temperature fluctuated between 98 and 102°F for thirty-five of the forty days he remained there. On the third day another x-ray film of the chest showed a marked increase in the size of the heart shadow, with increase of the pulmonary vascular markings. Symptomatically he improved considerably while taking salicylates, and they were continued throughout his stay, except for a period of one week. On the last three days in the hospital the pericardial fluid had subsided to such an extent that an apical systolic blow and a low rumbling diastolic blow were heard, the latter in the lateral decubitus position. He was dis-

charged home, where he remained on salicylates for several weeks and continued to improve, regaining both strength and ambition.

Three weeks before entering the Massachusetts General Hospital, the patient had a mild upper respiratory infection with cough, nausea and vomiting. He also complained of soreness over the right upper quadrant of the abdomen. Two weeks later he re-entered the outside hospital, complaining of moderate dyspnea and slight edema of the feet, ankles and legs, which disappeared after a few hours' rest in bed. There was mild but definite cyanosis. Physical examination revealed pleural fluid bilaterally. The heart beat was regular at 130, no friction rub and no murmurs were audible. An x-ray film of the chest showed fluid in both pleural cavities, more on the right side than on the left, with collapse of the right middle and lower lobes. The heart shadow was considerably smaller than at the original examination.

Examination of the blood revealed a red-cell count of 5,000,000, with a hemoglobin level of 100 per cent, and a white-cell count of 8700, with 68 per cent neutrophils. The nonprotein nitrogen was 44 mg per 100 cc. The urine gave a + test for albumin, and the sediment contained 3 to 5 red cells per high-power field. Six sputum specimens and the chest fluids were negative for acid-fast bacilli. Beta-hemolytic streptococci, alpha-hemolytic streptococci and *Staphylococcus aureus* grew from the sputum cultures. The chest fluid was sterile.

Two days after admission it was obvious that there was an increasing venous pressure, with engorgement of the neck vessels even in the sitting position. There was a paradoxical pulse. The systolic blood pressure was 105, the diastolic point was difficult to determine, but was thought to be 95. The pleural fluid had increased bilaterally. The liver was palpable three fingerbreadths below the costal margin but was nontender. There was a productive cough, and later the sputum became bloody. Paracenteses were performed twice on the right, with marked improvement in the respirations, although the venous engorgement persisted. A third paracentesis produced 800 cc of fluid, this time without the improvement that had been noted previously. On the seventh hospital day an attempt was made to obtain pericardial fluid. On inserting the needle into the fifth left interspace near the sternum, a definite grating sensation was felt just as the needle came in contact with the heart. Five cc of blood-tinged fluid was obtained. Another attempted paracentesis a little farther laterally in the same interspace failed to obtain fluid.

On the day of the pericardial paracentesis the patient was transferred to this hospital.

On arrival, he was breathing with great distress and was cyanotic, anxious and confused. Cyanosis was most marked in the hands and feet. The blood pressure and pulse were unobtainable. The skin was clammy. The neck veins were slightly distended,

without visible pulsations. Veins over the extremities were collapsed. The cardiac apical beat was not palpable, but to percussion the heart seemed enlarged about 10 cm. to the left of the midsternal line. The sounds were distant but regular at a rate of 80. There were dullness and decrease of breath sounds over both bases. No rales were heard. The liver extended 3 to 4 cm. below the costal margin and was tender. The sacral and scrotal regions were edematous. No reflexes could be obtained.

An x-ray film of the chest showed fluid in the left pleural cavity. The heart shadow had not changed since the last examination.

Two attempts were made to tap the pericardium through the xiphoid approach shortly after admission. No pericardial fluid was obtained. Death occurred a few hours after entry.

DIFFERENTIAL DIAGNOSIS

DR. GEORGE W. PICKERING.* This is quite clearly a case of acute pericarditis in a man of twenty-three. I suppose the possible causes of acute pericarditis in such an individual are first, rheumatic fever, second, tuberculosis and, third, some rather less common ones, such as a septic condition, an infarct of the heart and uremia. Cardiac infarct can be excluded. Uremia can also be ruled out without further discussion because of the blood chemistry and the subsequent course. I think that we can also exclude sepsis. We are not given any details about the pericardial fluid, but we know that the pleural fluid was sterile, that the blood culture was sterile and that there was no leukocytosis. That leaves, as the chief possibilities, rheumatic and tuberculous pericarditis.

Let us begin with the first episode, which is in the past history. He had a number of petit-mal attacks or, rather, attacks of unconsciousness that were thought to be petit-mal attacks. Unfortunately, we know very little about these attacks. We know nothing about the duration, the frequency and so forth, whether they were preceded by an aura, or whether they were preceded by any definite events in his environment. In other words, were they dizzy attacks or were they true petit-mal attacks? If they were epileptic attacks, we have no family history or symptoms of a cerebral lesion. I had thought this might possibly fit into tuberculosis — that these attacks might result from a tuberculoma of the brain. But I do not believe that we can say any more than that.

The next episode that he had was at the age of eighteen. He is now twenty-three and comes in with fever and upper respiratory infection and soreness of the left shoulder, which to my mind sounds like pain due to involvement of the phrenic nerve, but there is no evidence in the history of increase of pain with respiration, such as one gets in many cases when the diaphragm itself is involved, particularly on the pleural side. Then the signs on ad-

mission show quite clearly that he had an acute pericarditis. There was a friction rub, followed by enlargement of the heart shadow. This is actually the first x-ray film. There is a peculiar feature here, a thin arcuate calcification overlying the left border of the heart shadow. These are just visible but they are possibly about 3 or 4 mm. in from the edge of the heart shadow. It is tempting to speculate on these. They are not due to old cardiac infarction. They do suggest possibly that there had been a pre-existing pericarditis, and I should have guessed that tuberculosis was the cause of that. This film shows enlargement of the heart shadow, probably due to pericardial fluid, although I am not expert on radiologic diagnosis. This was obviously regarded at the time as rheumatic and was treated by salicylates. It is stated that he improved considerably while taking salicylates, but it is also stated that the temperature ranged between 98 and 102°F for thirty-five out of his forty days in the hospital, and my interpretation is that he did not respond to salicylates. That, I think, is the first point against rheumatic fever as a diagnosis. The second is that this was an adult, in most adults one would expect some symptoms and signs in the joints, but those were absent. There is one other point that I should like to comment on: if there were an effusion into the pericardium, I should have expected at that time that a marked increase in venous pressure would have been noted in the neck. There is no mention of that in the record. Then we come to the noises that were heard in the heart. After the fluid had started to subside, an apical systolic blow and a low, rumbling diastolic blow were heard, the latter in the lateral decubitus position. Did this mean valvular disease? I think Dr. Paul D. White and Dr. T. Duckett Jones[†] have shown here that one can get diastolic murmurs associated with cardiac enlargement. Does that then mean cardiac enlargement in this case, quite distinct from the pericardial fluid? If it does, then it argues for involvement of the heart muscle, which is strongly in favor of rheumatic heart disease. On the other hand, I think that it is rather difficult sometimes to distinguish a pericardial rub from a murmur, and I am not at all sure this may not have been a to-and-fro rub as opposed to the apical diastolic and rumbling diastolic blow reported.

The patient then went home and shortly afterward returned to this same hospital, where he was found to have signs of venous congestion. At any rate, he had edema, although it is stated that the venous pressure did not rise until two days after admission. I suspect that it was present on admission. He had fluid in both pleural cavities, with collapse of the right middle and lower lobes. He did not have anemia, the hemoglobin being 100 per cent, that is against rheumatic disease. There

[†]Bland, E. L., White, P. D., and Jones, T. D. Development of mitral stenosis in young people: discussion of frequent misinterpretation of mitral regurgitation murmur at cardiac per. *Am Heart J* 10:995-1001 1935.

*Professor of medicine, University of London.

was no leukocytosis. We have not heard anything about that before, it is slightly against rheumatic disease. The case was clearly being regarded as one of possible tuberculosis, because the sputum was examined repeatedly. The specimens were negative for acid-fast bacilli, and that is the rule in tuberculous pericarditis. Fluid was obtained from the pericardium, but unfortunately we are told nothing about it. I think we can assume that it was not a septic fluid. The patient got worse following the dry taps, was admitted to this hospital and perished within a few hours.

My diagnosis is tuberculous pericarditis. I think that it was acute, but possibly there had been some older element, because of the calcifications in the x-ray films. He probably had tuberculosis of the lung to account for the bloody sputum toward the end of his existence. He may have had tuberculoma of the brain, although there is only the very slightest indication for it. He probably died of terminal miliary spread, because that is the usual course in most cases. You will note that there is no definite evidence for that diagnosis. It is simply suggested because most cases of pericarditis that I have seen occurring in young adults and children with no other evidence of rheumatic disease, with no other evidence of involvement of anything else but the pericardium, with no etiologic factor discernible from examination of the fluid and with a duration of four months or more, have usually turned out to be tuberculous.

DR TRACY B. MALLORY: Would you like to give your impression, Dr. Williams?

DR CONGER WILLIAMS: At the time of admission our problem was treatment of the emergency. The patient was actually in a state of shock. No pulse was perceptible. He was deeply cyanotic, especially in the legs and hands. Of course our first consideration was cardiac tamponade to explain this picture, but one thing that bothered me about that diagnosis was the absence of marked distention of the neck veins. Dr. DuToit suggested that perhaps the absence of distended neck veins could be explained by diminished cardiac output. We also considered the possibility of an advanced rheumatic myocarditis with peripheral vascular collapse, because of the previous story of murmurs. Nevertheless, we thought there was an excellent chance that this man had pericardial tamponade and should, therefore, be tapped. This operation was performed by Dr. Soutter. He was unable to get any fluid from the pericardium. The patient died soon afterward.

DR PAUL I. WHITE: May I ask if there is certainty that the calcification is in the pericardium or in the heart and not elsewhere?

DR TOUFIC H. KALIL: Not without fluoroscopy. These films were done on the outside, and a lateral film was not taken. That may well be behind the heart.

DR WHITE: I should like to point out that it is possible to have both pericarditis of a chronic constrictive nature, possibly tuberculous in origin, and rheumatic heart disease in the same case. We have seen such cases but they are few and far between and apparently coincidental.

Dr. Pickering has looked up and seen quite a few cases of tuberculous pericarditis, and I should like to ask him whether the heart is enlarged in those cases and whether the subjacent or subpericardial myocarditis is diffuse enough to give the picture of an enlarged heart and to produce murmurs with no specific changes in the electrocardiogram. Of course the changes often found in the electrocardiograms in such cases are in part due to the subpericardial myocarditis, but perhaps there is more than that. In our chronic constrictive pericarditis cases there was cardiac enlargement in something over half. It seems as if the myocardium, as well as the pericardium, was involved.

DR PICKERING: I am not sure that I can answer that. I am certain that the myocardium is abnormal. At any rate, by the time the fluid is absorbed in tuberculous pericarditis it certainly behaves like that, in the sense that it does not respond in the ordinary way to changes in venous pressure, and my "pathologist friends" tell me that the myocardium looks abnormal. Nor am I able to answer the question regarding the heart size. We really see so few of these that we only get definite evidence about the size of the heart if we replace the fluid with air or if the patient is examined post mortem.

DR EDWARD F. BLAND: Would Dr. Pickering accept the migrating pleuritis, in addition to the pericarditis, as favoring an acid-fast background?

DR PICKERING: If you can accept this as an inflammatory pleural effusion, certainly. The difficulty is, I suspect, that you have throughout this case a congestion arising from pericardial tamponade or changes in the pericardial cavity, and it is difficult, I think, without seeing the patient and personally examining him from all these angles, to come to this conclusion. I think the explanation is correct but would not like to bank on it at the present time.

CLINICAL DIAGNOSIS

Rheumatic myocarditis
Cardiac tamponade?

DR PICKERING'S DIAGNOSIS

Tuberculous pericarditis, probably acute on a more chronic background and probably accompanied by pulmonary tuberculosis and possibly a terminal miliary spread.

ANATOMICAL DIAGNOSES

Acute and chronic tuberculous pericarditis
Tuberculosis of lung and bronchial and mesenteric lymph nodes

PATHOLOGICAL DISCUSSION

DR MALLORY Post-mortem examination showed a pericardium 5 to 10 mm in thickness, the thickening being due almost entirely to fibrosis, although there were a few spots with slight calcification of the pericardial sac. Approximately half the pericardial cavity was obliterated. There was a pericardial space left in two pockets amounting to a third or a half of the original sac. In that, we found just a few cubic centimeters of blood-stained fluid that did not seem to be enough fluid to consider that he had cardiac tamponade. The heart itself was very small, the heart and pericardium together weighed 450 gm. We have not separated the heart from the pericardium, but I doubt very much if the heart weighed over 275 gm. it might even be 250 gm. The valves were entirely normal. We found a number of large caseous bronchial lymph nodes, one caseous node in the mesenteric area and one small focus of active tuberculosis in the lung but no general miliary process. Sections from the pericardium and epicardium showed extremely marked fibrous thickening and inflammatory changes, and just beneath the epicardium in one spot a rather characteristic single miliary tubercle. I think we have enough to confirm the diagnosis of tuberculous pericarditis beyond a doubt.

Addendum by Dr Pickering I find this case of peculiar interest. A week previously I had communicated in the Ether Dome the results of work by Dr T Holmes Sellers, Dr G W S Andrews and myself, which had led us to conclude that, in Great Britain at least, most cases of constrictive pericarditis are of tuberculous origin. Briefly we observed the following: that out of 16 cases of tuberculous pericarditis observed over periods up to six years, 14 developed signs of constrictive pericarditis, 1 presented a persistent effusion and in only 1 was there no residual sign of pericardial disease, that acute tuberculous pericarditis unassociated with tuberculous pleurisy or ascites may give rise to relatively little subjective disturbance, and that the only 2 of our 7 patients with septic pericarditis who recovered from the acute stage presented no signs of constrictive pericarditis clinically or radiologically during the next four years. Calcification of the pericardium is common in constrictive pericarditis, this is the first case known to me personally in which post-mortem examination has revealed clearly both pericardial calcification and tuberculous pericarditis. It therefore adds weight to my belief that tuberculous is a common, and I think by far the most frequent, cause of constrictive pericarditis.

CASE 33392

PRESENTATION OF CASE

First admission A fifty-one-year-old woman entered the hospital complaining of epigastric pain, nausea and vomiting of five months duration. The

pain was not related to meals and not relieved by food. Tarry stools had occasionally been noted. Fifteen years before admission a posterior gastroenterostomy for ulcer and a cholecystectomy had been performed. From this time until six months before entry the patient had been relatively free of ulcer symptoms.

Physical examination was essentially negative.

Examination of the blood revealed a red-cell count of 4,200,000, with a hemoglobin of 60 per cent, and a white-cell count of 8000. The urine was clear, but the sediment contained numerous red cells. Subsequently, four other examinations of the urine were negative. The stools were guaiac negative on three occasions. The gastric acidity was normal.

A gastrointestinal series showed no active ulcer. The left kidney appeared enlarged. Intravenous and retrograde pyelograms showed a mass in the upper left kidney. An x-ray film of the chest was normal. The patient was transferred to the Urological Service, where the left kidney was removed through a lumbar incision. The upper pole of the kidney was occupied by a 8.0-cm by 5.5-cm renal-cell tumor (hypernephroma), which had not broken through the kidney capsule.

Second admission (thirteen years later) The patient was asymptomatic until three months before admission, when grossly bloody bowel movements had appeared. At other times the stools were black. For two months she had been weak and tired, with some pain in the left lower quadrant. She sometimes felt a lump in the left lower quadrant. The epigastric pain also recurred and was relieved by food. Three weeks before entry a barium enema at another hospital had shown a "bowel tumor."

Physical examination revealed tenderness in the left lower quadrant, which prevented deep palpation. No mass was felt.

The urine was normal, as were the nonprotein nitrogen, serum protein and prothrombin time. The hemoglobin level was 12.4 gm.

Examination of the x-ray films brought in by the patient showed a shadow the size of a kidney in the left upper portion of the abdomen. A barium enema disclosed a persistent filling defect in the descending colon that had the appearance of a polypoid neoplasm (Fig 1). There was no obstruction to the passage of barium. The bones were normal.

On the fifth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR LAURENCE L. ROBBINS In summary, this sixty-four-year-old woman had been complaining of bloody bowel movements for three months. There were associated symptoms of weakness, dizziness and left-lower-quadrant pain, with an abdominal mass at one time or another. At thirty-six years of age a gastroenterostomy and cholecystectomy

had been performed, and at fifty-one a hypernephroma of the left kidney had been removed

The first point that we can be sure of, in looking at this x-ray film, is that a barium enema had been given, and I should say that the patient was not particularly well prepared. There is a shadow extending well beyond the bowel, it apparently lies in close contact with the descending colon. Extending into the lumen of the descending colon is a small

There is, in addition, another shadow—a rather well defined mass—in the region where the left kidney is usually located

I should like to take this opportunity to point out the fact that frequently after nephrectomy a shadow is visible on the plain film of the abdomen that is perfectly consistent with a normal kidney shadow. That is probably what happened in the case under discussion. At least, I assume that the shadow is

FIGURE 1 Roentgenogram following a Barium Enema
The upper arrows point to the shadow described as lying in the kidney bed. The lower arrows indicate the mass involving the descending colon.

lobular mass, which is perhaps better seen on this film. I do not know whether this is a postevacuation study or not, but gas, which is not seen in this first film, is present and the film probably represents a double-contrast enema after the injection of air. Here again we see the mass. Most of my discussion will hinge on whether this shadow beyond the confines of the bowel and this one protruding into the lumen of the bowel are parts of the same lesion

due to organized blood clot or fibrous tissue that remained after operation. But the fact that there is a shadow in that area does not mean that the kidney was not removed and that another abnormality was present.

DR. BENJAMIN CASTLEMAN: How long does this shadow remain?

DR. ROBBINS: For years. I cannot be certain because there is no plain film, but I think that this

particular shadow corresponds to the persistent postoperative one frequently seen

To go back to the lower shadow protruding into the descending colon, could this have been tied up with some inflammatory process such as a stromal ulcer with abscess formation and perforation into the colon? It seems unlikely from the data in the history. Likewise, I do not believe that other inflammatory processes, such as hyperplastic tuberculosis and amebic granuloma, need be considered. An infected diverticulum could give this appearance, but there is slightly more lobulation and more protrusion into the lumen than one would expect in diverticulitis. Also, there is no other evidence of diverticulum that can be seen on these films. One should consider a foreign body as a possibility, but that again seems unlikely. Endometriosis can produce a shadow similar to this, but it is somewhat higher than is usually found and, at the age of this patient, endometriosis is improbable. Furthermore, endometriosis would not account for the melena.

So far as tumor is concerned, the first thing to consider is whether this was an adenomatous polyp, which immediately means cancer until proved otherwise. Or was this extrinsic shadow a secondary tumor that extended from a primary cancer in the bowel? That is not impossible, although it is extremely unusual, from the x-ray standpoint, to see a sharply circumscribed mass of nodes adjacent to the tumor. This is much too smooth for the ordinary mass of lymph nodes, so that I am inclined to rule out the possibility of a primary carcinoma.

Could this have been metastasis or extension from the hypernephroma? The mass was somewhat lower than the area in which the descending colon was in contact with the kidney bed, metastasis would not be impossible, however, and it is difficult to be certain of the observation from the number of films at hand. I shall take the chance that the mass involving the bowel was entirely intraperitoneal, because if this mass arose from the kidney area and extended to the bowel, I think that the shadow of the psoas muscle would have been lost in that area where the mass overlies it, and the shadow of the psoas muscle is present. I cannot exclude metastasis from hypernephroma, but I have not seen cases in which the bowel was involved.

Certainly, we must consider the possibility of lymphoma. Here, again, unless it arose from the nodes in the mesentery or the mesocolon and extended into the bowel, this appearance is atypical. It could have arisen from the small bowel, but there is nothing in the history or the x-ray films to indicate small-bowel disease. Finally, it is somewhat more of a polypoid lesion than the usual lymphomatous involvement of the bowel.

Tumors of connective-tissue or smooth-muscle origin certainly cannot be completely excluded. The mass is relatively smooth and appears to be intra-

mural and to involve the mucosa. These tumors are prone to bleed rather profusely, as this one did.

There is another tumor that should be considered purely from what is seen on these films—that is, a carcinoid. Often the bulk of the tumor lies outside the bowel wall, producing in many cases a fairly sharply circumscribed mass that may be smooth. By and large, however, the lesions do not involve the mucosa, and there is no bleeding in the cases with which I am familiar. Also, the history in this case was too short, because a carcinoid usually is a slowly growing tumor. I have never seen one in this location in the bowel.

Actually, this is as far as I have a right to go. All I can say is that there was a tumor that involved the mucosa and a large mass extrinsic to the bowel. If this problem could be studied from spot films, even though fluoroscopy was excluded, there would be more opportunity of determining what this mass was.

From now on whatever I say is pure guesswork. I believe that there are three things to be considered primarily: extension from a hypernephroma, tumor of connective-tissue or smooth-muscle origin and carcinoid. I do not believe that we need to consider a primary carcinoma or lymphoma seriously. I believe that the most probable diagnosis is a tumor of connective-tissue or smooth-muscle origin.

DR FLETCHER H. COLBY: I wonder why a chest film had not been taken. The lung is the favorite site for hypernephromas to metastasize.

DR CASTLEMAN: Chest films taken in the Follow-Up Clinic in the Out Patient Department three years previously were negative. The patient had not been seen since that time.

DR WILLIAM CLARK: Has recurrence of hypernephroma been recorded in that long an interval?

DR ROBBINS: Yes.

CLINICAL DIAGNOSIS

Tumor of descending colon

DR ROBBINS'S DIAGNOSIS

Spindle-cell tumor of descending colon

ANATOMICAL DIAGNOSES

Leiomyoma of descending colon

Pecurrent renal-cell carcinoma, with invasion of adrenal gland

PATHOLOGICAL DISCUSSION

DR CASTLEMAN: Fairly extensive adhesions were found throughout the left side of the abdomen. The left colon, which contained a mass the size of a baseball, was freed laterally, and another mass was felt slightly higher in the left gutter. At first it was believed that this second mass was located in the pancreas, but on further dissection it proved to be in the adrenal gland. The entire mass was removed.

Grossly, it measured 9 by 5 by 3 cm (Fig 2 and 3), and microscopically it proved to be renal-cell carcinoma involving the adrenal gland

The colon was then resected The intraluminal portion of the intestinal tumor was relatively small,

sent merely the site of the previous nephrectomy, was the recurrence of the hypernephroma

ROBERT NASON NYE

AGAIN, within a short space of time, the *New England Journal of Medicine* announces with sorrow the passing of a leader Dr Robert Nason Nye, its managing editor since 1937, succumbed on September 10 to an illness that, insidious in its onset and inevitable in its conclusion, was mercifully brief.

Dr Nye assumed the editorship of the *Journal* in 1937 on the retirement of Dr Walter Prentice Bowers, whose death a few weeks ago was recorded on this page. Where Dr Bowers left off Dr Nye began his own task, and gave to the *Journal* a skilled and devoted guidance that has brought it to a leading position among the medical periodicals of the world.

There are certain characteristics that distinguished Dr Nye from lesser individuals—his robust personality, his clear understanding, his intellectual integrity. He never compromised with his conscience. In the shock of his loss we realize that we shall not soon find one to take his place.

TOXICITY OF STREPTOMYCIN

FROM the reports of its clinical use to date^{1, 2} it is apparent that streptomycin will remain the treatment of choice in many infections due to gram-negative bacilli and to *Mycobacterium tuberculosis* until a better agent is found to replace it. The major drawbacks to its more widespread use, aside from its high cost, are the frequency with which development of bacterial resistance appears during its administration and the toxic effects that it produces, particularly when it is used in large doses or over long periods. Some reports dealing particularly with the otic complications of streptomycin have already appeared.^{3, 4} Detailed observations of the toxic effects of this agent in a small group of patients who were treated for tuberculosis over long periods at the New York Hospital are particularly worthy of comment.⁵

The patients received 3 gm daily in eight intramuscular doses of 375 mg each of an almost pure streptomycin salt. The levels of streptomycin in the serum ranged between 7 and 30 microgm per cubic centimeter at the end of the three-hour interval between injections. It was considered advisable to interrupt treatment because of toxic manifestations in only 2 patients, both had an anaphylactic type of reaction, and in each case it was possible to resume treatment later.

There was remarkably little irritation at the site of the intramuscular injections in spite of their large number and frequency. Repeated intrathecal injections of 0.1 gm in 10 cc of isotonic salt solution were also well tolerated. There was usually a moderate pleocytosis from these injections in patients who had no evidence of central nervous-system disease, and occasionally there was headache, nausea and vomiting or some pain in the legs, the latter presumably due to transient irritation of nerve

roots Amounts of 0.2 to 0.375 gm intrathecally, however, produced untoward reactions, particularly after such doses had been given repeatedly for several weeks. In such cases there was somnolence, slowing of the respiratory rate and retention of urine. These symptoms usually lasted twelve to twenty-four hours and then disappeared. There were no sensory changes or persistent sphincteric disorders. Nystagmus was occasionally noted immediately after the intrathecal injection. Appreciable concentrations (4.5 to 17 units per cc) of streptomycin were always present in the cerebrospinal fluid forty-eight hours after the intrathecal injection of these large doses.

Symptoms of vestibular dysfunction of variable severity appeared uniformly between the seventeenth and the twenty-fifth day of treatment. Complete symptomatic recovery eventually occurred in all subjects. This recovery was presumably a result of activation of compensatory mechanisms rather than of restoration of labyrinthine function.

Deafness developed in 2 of 16 patients treated for four months, and in 3 others subsequently treated with the same preparations of streptomycin. Bilateral nerve deafness, amounting to from 50 to 100 per cent, occurred in 7 of the first 100 patients treated with streptomycin at the New York Hospital.⁶ No tinnitus or impairment of hearing during or subsequent to the streptomycin treatment was observed in any of the other subjects, and no other neurologic disturbances were discovered in these patients. Five of the 7 patients with deafness had undergone prolonged intrathecal administration of streptomycin, and the other 2 had marked renal insufficiency, suggesting that the concentration of streptomycin in the central nervous system may be an important factor in the occurrence of deafness. Preliminary studies suggest that the site of this toxic reaction is the brain and that it is associated with liquefaction necrosis of the ventral cochlear and inferior vestibular nuclei.⁷ Since these patients may also have had central-nervous-system lesions, the part played by such lesions, at least in the deafness, cannot be ruled out.

The vestibular disturbance accompanying streptomycin therapy is a most unusual complication of drug therapy. Farrington et al.⁵ describe this disturbance as follows:

This reaction is characterized by the appearance of a mild headache, which disappears within twenty-four hours and is followed by the development of symptoms which resemble vertigo. The sensations differ from vertigo in that they seem to occur in a linear rather than a circular plane. At the completion of a sudden movement, such as reaching for an object, sitting up or leaning to one side, the afflicted person feels as though the movement was continuing in the same direction in which it had been going. Thus he experiences the sensation either of past pointing or of falling in the direction of the previous movement. Occasionally, a momentary delay in focusing the eyes after a sudden change in position will be noted. At the height of the reaction one patient displayed striking pendulum movements, similar to those observed in labyrinthectomized animals. When he assumed the erect sitting position suddenly, he swayed back and forth rhythmically for approximately sixty seconds.

There was a considerable variation in the intensity of the vestibular dysfunction experienced by the different subjects. At the peak of the reaction these subjects [the ones with moderate or severe involvement] were unable to sit up in bed unassisted and with the slightest motion were acutely uncomfortable even when lying flat. They were frequently nauseated, and occasionally they vomited. The symptoms usually persisted in an acute form for seven to ten days and then subsided almost entirely. The disappearance of the acute symptoms occurred with striking rapidity, sometimes within a period of twenty-four hours. In no instance, however, did complete recovery occur with the subsidence of the acute symptoms. Instead, the subjects entered into a phase in which the symptom was absent during ordinary activity but could be evoked momentarily by an unusual stimulus, such as an abrupt shaking of the head.

In general the stage of latent vestibular dysfunction persisted for approximately sixty days and then disappeared. During the fourth month of therapy all subjects except one were completely free from these symptoms while reclining or sitting erect in bed. Ataxia was absent as long as these persons could orient themselves visually with any fixed object. A staggering gait was present, however, when they attempted to walk in the dark or with closed eyes. In these particular instances the symptom has not been disabling and has slowly diminished in intensity during the nine months since the cessation of therapy. In no instance was streptomycin therapy interrupted because of vestibular dysfunction.

nystagmus was seldom encountered. Only one patient manifested a sustained nystagmus, although in several other subjects fleeting nystagmoid movements of questionable significance were observed. In [another] patient a rotary nystagmus was observed.

The renal complications, although not severe and probably of no great significance, are nevertheless of some interest. A few patients showed transient reduction in renal function associated with nitrogen retention. Casts of various types appeared intermittently in the urine in the majority of cases; they were present when a highly acid urine was excreted and usually disappeared when the urine was alkaline.

Sensitization reactions were encountered oftener during treatment with streptomycin than with sulfonamides or penicillin. They were manifested chiefly by fever, dermatitis and eosinophilia. The last was either intermittent or sustained, ranged from 5 to 39 per cent and was noted in the great majority of the cases.

McDermott⁶ also studied patients treated with impure lots of streptomycin. From a comparison of the reactions in such cases with those observed in patients treated with pure streptomycin it was concluded that the histamine-like reactions, irritations at the sites of injection and possibly sustained febrile reactions were not caused by streptomycin but by impurities, which are removable by refinements in the process of manufacture. All the other manifestations of toxicity that have been observed after the use of impure streptomycin have also occurred during the administration of the highly purified preparation of the drug.

From these observations, McDermott concluded that the immediate toxicity of highly purified streptomycin on long-continued administration is sufficiently low to justify the use of the drug in the treatment of serious and protracted infections, such as most forms of tuberculosis. Since streptomycin, however, can produce serious toxic reactions he believes that it is not advisable to use the drug in the treatment of benign infections with a generally favorable prognosis, such as minimal pulmonary tuberculosis and chronic brucellosis.

"MERCY CARS"

THE accounts that appear in the daily press from time to time describing the record-breaking speed made by so-called "mercy cars" on their way to

one or another of the large metropolitan hospitals, accompanied by police escort and heralded by the wailing of sirens, are to be deplored. Physicians who, in their early years of training, were driven through city streets in a hospital ambulance appreciate the thrill of such a journey, not only to those in charge of the ambulance but also at times to the patient. And who does not pause, with a certain boyish thrill, to watch an ambulance go by? Ever so often, however, this excessive and, as a rule, unnecessary speed results in death or serious injury to the occupants or to innocent bystanders.

Racing over congested highways does shorten the trip to the hospital, but it is only occasionally that the minutes gained are of benefit to the patient, indeed, such a trip may be truly harmful to one who is seriously ill. Thus, a physician, when he learned that a patient with a compound fracture of the skull was being rushed to his hospital under police escort, sent out word through appropriate channels that the police escort was to slow the ambulance down to below thirty miles an hour, believing that this was better for the patient and all concerned. He then took pains to be sure that the necessary measures to ensure immediate treatment on arrival at the hospital were taken.

The matter has its entertaining side. Recently, a small patient who had swallowed a penny was being rushed to a metropolitan hospital. En route, the automobile was in collision with another, and five occupants of the cars were taken to a small local hospital because of minor injuries. On arrival at the hospital the penny was found on the floor of the mercy car. Whether the shaking up of the ride or that of the accident was the effective therapy was not discovered. But neither, as a matter of fact, is recommended as a specific form of treatment in similar cases.

Certainly, a speed of eighty or even sixty miles an hour over roads, summer or winter, is difficult to justify except in extreme cases, and the attending publicity, even though no accident results, seems in poor taste. Such publicity should be minimized, and better still, the public should be made aware of the fact that, generally speaking, extreme speed is unnecessary and may be harmful to the patient and to others.

A HUNDRED YEARS AGO

With the multiplication of hospitals, dispensaries and charities of all descriptions, and the onward and upward march of pure medical science, there have grown into notice, and favor, too, institutions for providing families with the necessities of life, when the strong arm on which a wife and children placed their whole dependence for daily bread, is weakened, and the willing heart is overcome with assaults of disease. There is an office in Tremont street, where by the payment of from four dollars seventy-five cents to nine dollars fifty cents a year, a man, from twenty-five to fifty-two years of age, may draw weekly from four to six dollars, when an invalid. Besides the great benefit to the insured, there would be no complaint by the physician of poor practice by loss of bills, were the custom a general one, as it should be, of being fully insured. A scheme so admirable as this, and withal so strictly economical, addresses itself at once to the understanding, and we hope, therefore, that the benefits of that excellent institution, the Massachusetts Health Insurance Company, may be appreciated by the intelligent people of New England — Mr L M S, while engaged in his usual avocations, was attacked with severe pains in his bowels, and nausea, at noon. He was obliged to leave his business and return home. The pain was in the right hypogastric region, not constant, but intermitting, like colic pain. He took a cathartic, which was retained in the stomach three hours and a half, and was then vomited, without having any effect on the bowels. An enema was ordered, which moved the bowels freely, with much relief. In two or three hours after the enema, the spasmodic pain returned in the same spot on the right side, shooting through to the back. It became necessary to resort to opiates every few hours to relieve pain. He continued to vomit frequently, at first dark mucus and such drinks as he had taken, and finally vomitus colored by particles of dark blood. His pulse became more rapid and less distinct, his skin moist and cool. He continued to fail until he breathed his last. An autopsy was made by Dr J B S Jackson. The caecum and ileum were highly inflamed, but the cause of the inflammation was not discovered till the caecum was dissected from its bed in the iliac fossa, the appendix then was found closely adherent to the caecum, in an ulcerated and gangrenous condition. Within the appendix were two small masses of fecal matter in a hardened condition, these had ulcerated completely through the coat of the appendix. How long the appendix had been in this unnatural condition, it is impossible to say. It was probably of long standing, but not congenital. He had for the last three

or four years complained of pain and lameness in that region when more than usually fatigued, as to the length of time the fecal matter had been retained, no definite opinion can be given — Readers will doubtless recollect that a variety of comments appeared in this Journal on the dinner served up for the Massachusetts Medical Society. At the last anniversary it is believed the dinner proved quite satisfactory. It seems, however, that something more is wanted to give a gusto to the festivities of the occasion. A gentleman declares that a band of music is the one thing needful to give life to a very dull meeting. The mere act of eating oyster pie and fried cabbage is not sufficiently animating to stir up the enthusiasm of four hundred physicians. So next year he votes for music — Dysenteric affections are very general as they always are at the season of the coming in of new fruits, yet the number of deaths has been comparatively small, which gives reason to suppose that physicians, when seasonably consulted, have been successful in their prescriptions — Otis Clapp, of Boston, has in press a "New Manual of Veterinary Medicine on the Homeopathic Treatment of the Horse, the Ox, the Sheep and the Dog and other Domestic Animals," by F A Gunther. Translated from the third German edition, with considerable additions. Surely this is an exhibition of folly, remarkable even in imaginary science — John U Haezer, of Sullivan Co, Tenn, aged 114, walked recently, half a mile to vote! He has voted at every presidential election that has been held in the United States — The American Geological Society was in session in Boston last week at the Marlboro' Chapel. There was a strong representation of the science of the country present. It was noticeable that quite a number, if not a majority of the Society hailed from the medical profession. The true way of keeping up an interest in any branch of natural science is to bring those together frequently who are devoted to such pursuits. It is only by common labors and freely interchanging thoughts, that progress can be made in elevated branches of knowledge — An eminent physician of New Orleans was called recently, it is said, to Madame A, 1 of a slight fever. He wrote a prescription, the directions of which were followed strictly, and a short time only after the medicine for Madame A was taken, she expired. It subsequently appeared that he had ordered *morphine* instead of *quinine*. The error, which is only explained by the distraction arising from the pressure of professional engagements, is irreparable — Extracted from the *Boston Medical and Surgical Journal* August-September 1847

WALTER PRENTICE BOWERS

1855-1947

Walter Prentice Bowers was born in Cluton, Massachusetts, on May 19, 1855, one of the eight children of the Reverend Charles Manning and Ella (Damon) Bowers. At the time of his birth his father's yearly salary as minister of the First Baptist Church was five hundred dollars. At no time did it permit any unusual expenditures on the education of so large a family, and the three years after Walter's graduation from high school found him working in a drugstore, earning the money to put himself through Harvard Medical School.

He matriculated in the school in 1876 and graduated with honors in 1879. After serving for a time in the Out Patient Department of the Massachusetts General Hospital, he joined the staff of the Worcester Lunatic Hospital, now the Worcester State Hospital and settled in Lancaster to practice. Ill health forced him to resign from this post in 1881, and he moved to Clinton, where he established the practice that was to occupy him continuously until his death. In 1880 he married Helen M. Burdett, of Clinton, whom he survived. They had no children.

Dr. Bowers was in every way a leading citizen of his community. He founded the Clinton Hospital in 1889 and was president of its association for fifty years, even in the past year he had led the successful campaign to raise funds for its new building. He had been a member of the Board of Selectmen, town-meeting moderator, a member of the Board of Health, vice-president of the Clinton Trust Company and a director of the Clinton Savings Bank.

In 1894 he became a member of the Massachusetts Board of Registration in Medicine, and in 1913 its secretary. He had been a counselor of the Massachusetts Medical Society since 1898 and was president from 1912 to 1914. He was presi-

dent of the Worcester District Medical Society in 1903.

In 1920 Dr. Bowers was active in effecting the purchase by the Society of the *Boston Medical and Surgical Journal*, then in an honorable but impecunious decline. He became its managing editor in the following year, thus assuming an added responsibility that necessitated his retirement from the secretaryship of the Board of Registration in 1922, a year before he would have been eligible for a pension. During his editorship, which he held until 1937, he brought the *Journal* back to a position of national prominence, fully justifying its purchase by the Society.

We all knew Dr. Bowers as an uncompromising advocate of the best type of medical practice, as a tireless worker in behalf of the Massachusetts Medical Society and as a leading medical journalist. His community knew him as a public-spirited citizen and as a skillful, devoted practitioner of medicine. A smaller circle knew him

as an ardent sportsman, carrying his fishing rod with him in the spring and his gun in the fall on his long drives through his native countryside, and as the hunting companion of his old friend, the late Dr. E. Amory Codman. A few only knew of his hidden kindnesses, of the young people whom he had helped through school or college or of the aid that he had given to various younger colleagues in his profession.

In the whole conduct of his life he was the good physician, and it was as such that President Conant of Harvard University recognized him in conferring on him the honorary degree of master of arts in 1935, shortly after Dr. Bowers's eightieth birthday — "A physician devoted to his calling, for more than forty years a general practitioner in Worcester County, he has brought skill and wisdom to countless homes."

CORRESPONDENCE

INSTITUTE OF THE HISTORY OF MEDICINE

To the Editor An editorial that appeared in the May 22, 1947, issue of the *Journal* suggests for discussion several topics that are of great interest to the medical profession of Boston and New England. The title of the editorial is "New York Academy of Medicine," and the writer points out some of the activities of the New York institution, briefly compares Boston with New York and closes with a paragraph that I quote in full, underlining three words to which I wish to call attention

There is, *curiously*, no similar organization in New England, although the various functions of an academy are *adequately* carried on by the state medical societies, the medical schools and, notably, the Boston Medical Library, fellowship in which carries with it a dignity and an intellectual prestige that still have their value

"The various functions of an academy are *adequately* carried on by *notably* the Boston Medical Library." As I understood the situation, the basis for the appeal by the Boston Medical Library to the Massachusetts Medical Society for assistance was that the services actually rendered by the Library were notably inadequate

I quote from the Fleming report *A Factual Survey of the Medical Libraries in Boston*, dated 1941 but still pertinent, since little if any progress was made during the War. The first quotation is from the general section of this survey

The administration of Boston's medical libraries has not attained the general standards of library administration in evidence in the rest of the country. It is noticeable that the use made of Boston medical libraries has been generally less than that commonly reported elsewhere. Although many factors enter into this apparent difference in use, it is the opinion of this observer that the basic factors are the failure of the Boston medical libraries to provide (1) adequate reading facilities, (2) expert bibliographical and reference services, (3) instruction in the use of the library, (4) ready access to the literature, (5) messenger service between library and laboratory and (6) sufficient copies of heavily used material

Persons who use the Boston Medical Library may easily check on these points to see what is true of that institution

I quote also from the section of the report dealing with the Boston Medical Library.

Despite the magnificent resources which it has available, neither the support nor the use of the library has been up to expectations. (Some of the alleged trends are then noted.) If these assumptions are true, then support for the Boston Medical Library will continue to fall off, and this splendid collection, which is unexcelled in many fields and vitally essential for the practicing physician and research worker alike, will face a somewhat uncertain future. This library is now faced with the serious problem of adjusting itself to new conditions. Should it remain the "gentleman's" library of the past, where tradition still is the important factor, or should it expand its services to meet the changing conditions which confront it

The rather restrained Fleming report does not use the words "adequately" and "notably" to characterize the way in which the Boston Medical Library is carrying on its functions

The writer of the editorial says, "There is, *curiously*, no similar organization in New England," but he does not satisfy the curiosity of the medical profession whom he is addressing. There have been, to my knowledge, in the past thirty-five years, two serious and not insignificant movements to improve greatly what may be called briefly the general set-up involving the Boston Medical Library as the center. These came to nothing and local petty jealousies were a critical factor in preventing progress. The reason there is no such institution in New England is because there are not persons enough who care enough to do enough to create it.

Few persons who have given thought to the subject are satisfied with the situation as it exists. Not only is it confused and chaotic, but the wider and deeper implications that are involved receive almost no attention. Yet the "magnificent resources of the Boston Medical Library unexcelled in many fields," themselves a high tribute and a great memorial to the men in the past who loved books because "the chains of the mind are broken" by understanding of the past," lie there waiting for the magic touch of the historian to make them effective in leading us toward freedom

The most striking fact about the world today is the confusion, much of it due to the rapid rate of change. To make

adjustment to this new environment we need new ideas, new emphasis on and ways of using old ideas, new ways of escaping from old ideas that obstruct progress in our path toward freedom. Among the new ideas, which are sure to come, there will be many based on unrealistic thinking with the drive of emotional imbalance behind them. Some of these new ideas will be merely "old foes with a new face." They can be met, they must be met, with ideas based on realistic thinking, on a comprehensive and just evaluation of all the facts available, supported by sane and balanced emotional drives

Medicine cannot escape from the general confusion. It is at least a little off balance, owing chiefly to the dominance of the specialist, whose weakness is that he has lost perspective. This cannot be remedied by merely seeking the help of the general practitioner. What is needed is a reorientation of medicine itself in the light of the comprehensive view of the world, extensive and intensive, that is open before us today. How can we get a truer perspective?

"History," writes Lord Acton, "is a narrative told of ourselves, the record of a life which is our own, of efforts not yet abandoned to repose, of problems that still entangle the feet and vex the hearts of men. He adds, "History compels us to fasten on abiding issues and rescues us from the temporal and the transient."

It may be objected that the history of medicine is a brood reed on which to lean. It has but a small and relatively unimportant place in the medical curriculum and little part in university education today. The reply to this objection is that a different approach is needed. Do we find in the tradition of the English-speaking peoples that the writing of history has been the monopoly of university professors? We Gibbon and Grote and Macaulay and Lingard and Prescott and Motley and Bancroft and Lea, to name but a few, university schedules? Perhaps it would be well for writers of the history of medicine to break away from university entanglements

In summary, there is opportunity in Boston for further development of the sources of history, including a central reference library for all kinds of books that have to do with the healing art in any of its branches. In the interest of economy and efficiency, co-operation is desirable in a practicable way among all institutions needing medical libraries. Medical schools, hospitals and other institutions might reduce their libraries to the minimum compatible with the immediate working needs of the institution. Books not needed for the working library could be deposited in the central library. Facilities for the transportation of books are generally regarded as necessary

A critical need is that there be developed in the central library a division of research, under the direction of a professional historian expert in research and exposition. As an integral part of the organization and so endowed that research does not have to be stopped because an additional janitor is needed, such a department has great possibilities. It might be called the Institute of the History of Medicine if that seemed desirable. Bibliographic services are usually rendered by well equipped libraries. In an important sense, research should be the mainspring of the activities of the library and should be carried on at all times

There are needed adequate reading rooms and work rooms, large and small, and ample space and other facilities for medical activities now carried on in the Boston Medical Library, such as those of the Massachusetts Medical Society and its *New England Journal of Medicine*. Perhaps others would be added later. It is clear that the present buildings of the Boston Medical Library do not lend themselves to the development of a large auditorium and rooms appropriate for smaller meetings

What the project is called is of secondary importance. It might be planned to meet the present, and so far as can be foreseen, the future needs of the community, which in New England, for years to come. In any case it should be an outgrowth of community conditions to meet community needs, keeping in mind always the principle of seeing the part in the light of the whole. If this principle is followed the project might become of national importance, worthy of support by educational philanthropy

BOOK REVIEWS

Victory over Pain. A history of anesthesia. By Victor Robinson, M.D. 8, cloth 338 pp., with 17 illustrations and 10 plates. New York: Henry Sehnman, 1946. \$3.50

Dr. Robinson has written a history in a popular narrative form of the means used for the relief of pain and the production of surgical anesthesia from the time of antiquity when the Greeks and Romans used herbs for this purpose, to the present, when local anesthesia in its various forms is prevalent and the possibilities of ether are being investigated.

Half the volume is devoted to the discovery and development of surgical anesthesia, by ether and nitrous oxide in the United States and by chloroform in England, during the period 1832-1850. The facts relating to Long, Wells, Jackson and Morton are given in an impartial manner and Dr. Robinson wisely refrains from taking sides in the controversy which is still alive after a century has passed since Samuel Colt gave his exhibitions with laughing gas. The quip of Oliver Wendell Holmes that the wisest verdict in the matter "To (c)ther" is quoted as Dr. Robinson's judgment on the merits of the case.

Samuel Colt, of Hartford, Connecticut, inventor of the famous Colt revolver, gave exhibitions on the street corners in Ware, Massachusetts, in 1832, of the effects of laughing gas for the purpose of raising money to be used for expenses incidental to inventing his revolver. In the section on chloroform is related the story of Samuel Guthrie and the part he played in the discovery of chloroform coincidental with Sobbeira and Liebig in 1831.

The first part of the book presents a short summary of the subject in the classical, medieval and renaissance periods and the seventeenth to the early nineteenth centuries with chapters on Humphry Davy and nitrous oxide, Henry Hill Hickman and carbon dioxide and Mesmer and mesmerism. The last part is devoted to local, regional and refrigeration anesthesia, twilight sleep and complicated modern anesthesia apparatus. The text concludes with a bibliography that is nothing more than a short reading list of books used by the author in writing his history.

The book is well published except that some of the illustrations are not up to standard quality and is recommended for medical-history collections.

Therapeutic Exercise. By F. H. Ewerhardt, M.D., and Gertrude F. Riddle, B.S. R.N., R.P.T. 8" cloth 152 pp. Philadelphia: Lea and Febiger, 1947. \$2.50

In the preface the authors state that the purpose of this manual is to provide a text for students training in physical education, occupational therapy and physical therapy. These three groups are intensely interested in the motions that normally take place in the various joints of the body. The textbooks on which they depend to obtain this knowledge are as a rule of the type that deal with elementary anatomy and physiology. A comparatively small portion of these texts is devoted to motion. Some books discuss at length muscle action or body mechanics but such works are few and are not quite adequate. The appearance of this manual is therefore welcome.

It supplies information pertaining to joint motions. It suggests the proper exercises to preserve such functions in health and to restore them when they become subnormal or absent after disease or injury. This is carried out in detail. For example nine pages and eleven drawings are devoted to instruction in the use of the goniometer to measure angles or degrees of motion. Fourteen pages present a brief review of the plexuses of nerves in the upper and lower extremities, of the normal functions, the causes, signs and symptoms of their abnormal status, the tests to be employed in the determination of the extent of their dysfunction and the methods used to restore them to normalcy. In addition to the treatment of the upper and lower extremities the book deals with abnormal conditions of the abdominal muscles and curvatures of the back, suggesting the proper remedial exercises.

Poliomyelitis and spastic diseases are each given an entire chapter; that on the former deals at length with muscle function testing as well as muscle training whereas the latter discusses the medical, surgical and orthopedic aspects, together with exercise, vocational, recreational and physiotherapeutic measures for the restoration and co-ordination of the natural body mechanics.

Some of the valuable information scattered throughout the book could advantageously have been tabulated in one section serving as a source of ready reference. Thus, in the next edition the authors might consider the advisability of incorporating a table of the skeletal muscles, with their original insertions, nerve supplies and actions. Another omission comprises drawings, diagrams and cuts; their inclusion in coming editions will greatly add to the value of this book by making students visualize the body structures and their relations and functions.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Peter's Surgical Handicraft. A manual of surgical manipulations, minor surgery and other matters connected with the work of surgical dressers, house surgeons and practitioners. Edited by Hamilton Bailey, F.R.C.S. (Eng.), surgeon, Royal Northern Hospital, London; surgeon and urologist, County Hospital, Chatham; surgeon, Consolation Hospital, Lambeth; senior surgeon, St. Vincent's Clinic and Italian Hospital, and consulting surgeon, Metropolitan Ear, Nose and Throat Hospital, Potters Bar Hospital and Essex County Council. Fifteenth edition, fully revised. 8, cloth 668 pp. with 789 illustrations. Baltimore: Williams and Wilkins Company, 1947. \$7.00.

This standard British manual, the joint work of forty four authors has been revised to bring it up to date since the publication of the previous edition in 1944. Technical procedures have been depleted pictorially necessitating the addition of a large number of illustrations. The popularity of the manual is evidenced by the editions printed since the publication of the first edition in 1884. The volume is well published in every way and is a credit to its British printer.

A Manual of Otolaryngology, Rhinology and Laryngology. By Howard Charles Ballenger, M.D., associate professor and acting chairman, Department of Otolaryngology, Northwestern University School of Medicine and surgeon, Department of Otolaryngology, Evanston Hospital, Evanston, Illinois. Third edition, enlarged and revised. 8" cloth 352 pp. with 135 illustrations and three color plates. Philadelphia: Lea and Febiger, 1947. \$4.50.

This standard manual has been revised by the addition of new material and a chapter on headaches and neuralgias of the face and head. Illustrations on clinical anatomy have been added to the various sections. The text has been prepared primarily for undergraduate medical students but should prove useful to general practitioners and nurses.

Handbook of Medical Emergencies. Compiled by eight physicians who recently completed their internships, headed by Thomas B. Fitzpatrick, M.D. 16" cloth 106 pp. Lithoprinted. Cambridge: Harvard University Press, 1947. \$2.50.

This pocket-size manual the combined work of a committee of eight young physicians and a board of twenty three eminent specialists in various fields of medicine presents in complete outline form for quick reference the essential differential diagnostic points and procedures and specific and practical management of over three hundred acute medical emergencies. Included are the exact dosages, routes of administration and complications met with during the use of the various therapeutic agents. There are general chapters on penicillin, sulfonamide and parenteral therapy. Then, in order, are discussed the infectious diseases, diseases of allergy, intoxications, diseases due to physical agents and diseases of the various systems of the body. The volume is concluded with tables of equivalents of weights and measures and of normal values in blood, urine and spinal fluid; a list of abbreviations and an index. It should prove especially useful in the wards of hospitals. The presentation of some rare conditions, such as metallic, food and drug poisonings should make it valuable to the general practitioner.

Textbook of Medicine Edited by Sir John Conybeare, K B E, M C, D M (Oxon), F R C P, physician to Guy's Hospital 8°, cloth, 1170 pp., with 30 plates and 25 figures Baltimore Williams and Wilkins Company, 1946 (Printed in Great Britain) \$8 00

First published in 1929, this standard British textbook, which is the joint effort of seventeen contributors, has been revised to include material accumulated since the publication of the last edition in 1945. The articles on malaria, black-water fever, bacillary dysentery and typhus have been largely rewritten. The article on heat has been rewritten and transferred to the section on tropical diseases. There is a new article on the menopause, and those on thyrotoxicosis and diseases of the pituitary body have been revised. A section on penicillin and an appendix on aviation medicine have been added.

P-Q-R-S-T A guide to electrocardiogram interpretation By Joseph E F Riseman, M D, associate in medicine, Harvard Medical School, instructor in medicine, Tufts College Medical School, and visiting physician, Beth Israel Hospital, Boston. Second edition. Oblong 16°, cloth, 84 pp., with 170 illustrations. New York Macmillan Company, 1947 \$3 50

This manual, first published in 1944, has been revised and reset.

Peripheral Vascular Diseases (Angiology) By Saul S Samuels, M D, consulting vascular surgeon, Long Beach Hospital, New York, attending vascular surgeon, Brooklyn Hospital for the Aged, and chief, Department of Peripheral Arterial Diseases, Stuyvesant Polyclinic Hospital, New York 8°, cloth, 85 pp., interleaved. New York Oxford University Press, 1947 \$2 50 (Oxford Medical Outline Series)

This outline of angiology should prove useful to students and physicians, since it furnishes in a compact form the essential facts necessary to an understanding of the various diseases of the peripheral vascular system. The material is well organized. The initial chapters deal with the anatomy of the blood vessels and the autonomic nervous system, classification and symptomatology and objective signs in general, followed by the various diseases — arteriosclerosis obliterans, thromboangiitis obliterans, Raynaud's disease, embolism, varicose veins and the rarer conditions. Each disease is discussed from the viewpoints of etiology, pathology, symptomatology, objective findings and treatment. A selected list of references is attached to each chapter.

Proceedings of the Eleventh Annual Convention of the National Gastroenterological Association 8°, paper, 187 pp., with 23 illustrations. New York Medical Authors' Publishing Company, 1947 \$2 50. Reprinted from *Review of Gastroenterology*.

This reprint makes available in one small volume the various papers on peptic ulcer, infectious hepatitis, psychosomatic medicine and gall-bladder disease read at the convention, held in New York City June 19-21, 1946.

Physiological and Psychological Factors in Sex Behavior By S Bernard Wortis, M D, and others 8°, paper, 42 pp. New York New York Academy of Sciences, 1947 50 cents. Reprinted from *Annals of the New York Academy of Sciences* (Vol XLVII).

This pamphlet contains a series of five papers that were read by authorities in their fields at a conference held by the Section of Biology and the Section of Psychology of the Academy on March 1, 1946. The material is divided into two parts: animal behavior and human behavior. In the first part the animal endocrines in relation to sexual behavior and sex behavior in primates are discussed, and the knowledge to date summarized. These papers are documented with lists of pertinent references to the literature of the subject. In the second part normal and aberrant sex behavior and sex culture are considered. Alfred C Kinsey, discussing sex behavior in the human animal, bases his conclusions on an extensive case-history study that has been under way at Indiana University during the past eight years, and has accumulated to date over ten thousand histories obtained by first-hand interviews with persons of wide social range, of all ages and of a diversity of backgrounds. The evidence seems to point to the fact that sex practices heretofore con-

sidered abnormal are normal in the pattern of biologic behavior. The papers are well written, clear in expression and succinct. The pamphlet is well published in every way and should be in all medical and social libraries and in the private collections of all persons interested in the scientific aspects of sex behavior.

NOTICES

MASSACHUSETTS MEMORIAL HOSPITALS

The Massachusetts Memorial Hospitals have opened its their Outpatient Department on East Concord Street a Seizure Clinic to be held on Thursday afternoons at 2 o'clock. This clinic will be under the charge of Drs Bernard Bandler and Charles Kaufman, of the Department of Psychiatry, Boston University School of Medicine. Appointments for patients wishing to attend this clinic may be made by telephone to the clinic secretary, Miss Cutter, at KENmore 9200.

AMERICAN ALLERGY FUND GRANTS-IN-AID FOR SCIENTIFIC RESEARCH

The American Allergy Fund, an organization for the advancement of medical science founded in Cleveland slightly more than a year ago, has announced that grants in aid for scientific research are available. The grants will be made to investigators in the biologic sciences, both medical and non-medical, whose problems meet the requirements of the Scientific Advisory Council; preference will be given to problems with immediate relation to allergy, although investigations in physiology, biochemistry, pharmacology, immunology, genetics and other basic sciences are solicited. Grants will be made for one year in amounts not to exceed \$3,500, and may be renewed from year to year if the work is progress warrants continuation.

Applications (seven copies) should be addressed to the American Allergy Fund, 525 Erie Building, Cleveland 15 Ohio (attention Scientific Council), and should contain the following information: a statement of specific research problems and an outline of the method or methods of procedure to be followed, a description of research facilities in the institution where the investigator will employ the grant, tentative budget, and a statement of the applicant's research record — accompanied, if possible, by publications or reprints.

A COMPARISON BETWEEN THE CLINICAL EFFECTS OF PYRIBENZAMINE AND THOSE OF BENADRYL*

MARY H. LOVELESS, M.D.,† AND HALLA BROWN, M.D.‡

NEW YORK CITY

ALTHOUGH twenty articles on the clinical effects of Benadryl have appeared in the American literature since early in 1946, when the drug was introduced, only five are to be found on Pyribenzamine. Feinberg and Friedlaender¹ are the only investigators who have made serious inquiry into the practical value of both drugs, and no statistics are available on the relative efficiency of these two agents in the same subject. Furthermore, their prophylactic and therapeutic possibilities in "constitutional" reactions to overdosage of allergenic extract have been examined in only 8 cases.² The purpose of the present report is to add observations on Pyribenzamine in 150 adult patients and on the practical use of Benadryl in 53, including cross-trials in 33 cases and the treatment of "constitutional" reactions with the histamine antagonists in 20.

MATERIALS AND METHODS

A majority of the patients were inpatients or outpatients complaining of hay fever, bronchial asthma or acute (often drug) urticaria, whereas a few had atopic dermatitis, chronic urticaria, dermatographism or acute serum reaction. Sixteen patients who had developed hay fever, asthma or cutaneous allergy directly after an overdose of therapeutic allergen were given one of the two antihistaminic drugs orally on twenty such occasions to determine its value.

The dose routinely prescribed was 50 mg. by mouth, to be repeated in one to four hours if symptoms persisted or recurred but not oftener than five times in any twenty-four-hour period. Usually, one such dose sufficed to control the symptoms for four hours, so that few patients ingested more than two or three a day. The drugs were restricted to symptomatic relief and were never employed prophylactically.

Many of the trials were initiated under our direct supervision or that of assistants, so that the results might be judged objectively as well as subjectively.

RESULTS

Clinical Effectiveness

Constitutional reaction. The disorder most susceptible to the drugs appeared to be the constitutional reaction that follows overdosage of allergic patients. If such responses were not of violent intensity, they almost invariably diminished or disappeared twenty or thirty minutes after the oral administration of 50 mg. of the histamine antagonist. The blanching of a brilliant erythema and the diminution of acute urticarial wheals were usually too rapid, once initiated, to resemble spontaneous resolution. Asthma was relatively refractory to the drugs as compared to nasal or cutaneous manifestations (Table I).

Twelve cases of mild systemic reaction were treated with Pyribenzamine. Three subjects who developed generalized erythema and slight wheezing lost the cutaneous signs and most of the bronchospasm twenty minutes after ingesting 50 mg. of the drug. Three others had similar manifestations, which were completely controlled. Another patient, with accidentally induced hay fever, showed complete recovery half an hour after the taking of a 50-mg. tablet, and a similar case was partially relieved. Pruritus of the eustachian tube and facial erythema that had followed an overdose yielded partially to a tablet of Pyribenzamine. The urticarial eruptions of 3 pollen-inoculated subjects responded spectacularly to the drug, and another patient required two hours for the clearing of the skin. Thus, there were complete responses in 8 and partial responses in 4 cases to a single 50-mg. dose of Pyribenzamine in 12 patients with constitutional reactions who received no other treatment (Table I).

The situation with accidentally induced asthma was less encouraging. When bronchospasm occurred

†Fellow in allergy, New York Hospital.

shortly after an inoculation of allergenic extract and was of marked intensity, Pyribenzamine was without effect in 2 of 4 cases. Adrenalin, however, brought prompt relief.

The 4 cases of systemic reactions treated with Benadryl by mouth appeared to respond as well as those treated with Pyribenzamine.

Acute urticaria was next in order of susceptibility to the antihistaminic agents. There were 27 cases of acute drug allergy, 21 being referable to penicillin and 2 to sulfonamides. Four patients lost not only the subjective discomfort but also the lesions. Eighteen ceased to itch and showed diminished cutaneous signs. One case of phenobarbital and 1 of novocain hypersensitivity showed partial im-

In another group of 8 patients with nonseasonal allergic rhinitis similar tendencies to yield to the drugs were shown in 6 cases. The number of observations was obviously too small for definite conclusions. This paucity of sampling likewise applies to the remainder of the data, which are presented mainly to add to the still inadequate figures available in the literature.

Other conditions. Extrinsic asthma treated with the drugs showed improvement in 7 of 11 cases, and intrinsic asthma responded partially in 3 of 9 cases. Of the 20 cases in which observations on asthma of all types were made, 50 per cent yielded to drug therapy, but in most cases the improvement was

provement, whereas a streptomycin rash and an exfoliative dermatitis due to gold therapy resisted all antihistamine therapy. Acute urticarial eruptions of unknown etiology in 2 of 4 cases responded spectacularly.

Successful attempts were made to control acute urticaria with Benadryl in 2 cases. Chronic urticaria yielded to treatment in over half the trials with the two drugs.

Allergic rhinitis of extrinsic seasonal variety (pollen hay fever) responded almost as well as the drug eruptions. Some of the patients in this class had received preseasonal therapy against ragweed hay fever. All were given small supplies of one of the drugs for use at such times as symptoms developed. Eighty-five per cent of the 60 patients in this group reported success with Pyribenzamine, 19 of these were subsequently given Benadryl for comparison, and all but 4 found the drugs equally effective. Nineteen other subjects were tested clinically with Benadryl alone and experienced relief comparable with that described after Pyribenzamine.

partial. Atopic dermatitis was even less responsive, the results being entirely negative in 4 patients and partial in 1, who noted that the pruritus was controlled. One of 2 subjects with pruritus due to obstructive jaundice also considered the subjective discomfort to have been alleviated after the administration of Pyribenzamine. The wheal, flare and pruritus of dermatographia were reduced if two tablets were administered fifteen minutes before the skin was traumatized with a fingernail stroke. Similarly, the drug afforded definite relief to a young woman who had developed generalized urticaria, angioneurotic edema and critical hypotension a few hours after having received antitetanic horse globulin, the intense itching and the tendency for the arterial tension to drop to shock levels were both controlled by hourly doses of 50 mg administered for four hours.

In general, the experience with these drugs makes it appear that they are most valuable in urticaria, hay fever and in systemic reactions to overdoses of allergenic solution.

Relative Efficacy in the Same Patient

Figure 1 indicates the results of trials in 33 patients in whom the effects of first one drug and then the other were established. In 23, the therapeutic influence of the two agents could not be distinguished. Among the remainder, half preferred one and half the other medication. In the group in which equal response to either drug was reported 4 patients detected no influence on their complaints, 7 reported partial control of symptoms, and 12 were

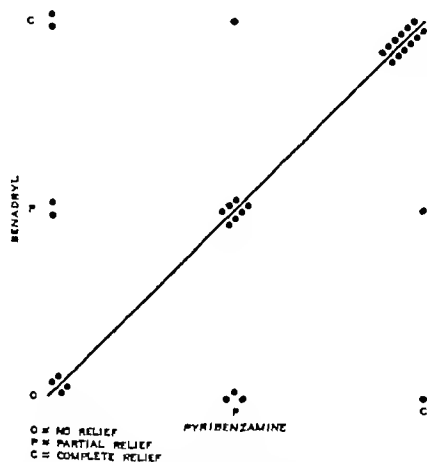

FIGURE 1 *Relative Efficiency of Pyribenzamine and Benadryl in Thirty-Three Patients*

completely relieved. So far as the type of complaint is concerned, 20 subjects in this experiment were ragweed sensitive, 3 exhibited systemic reactions to therapeutic injections, and the remainder were given the histamine antagonists for such conditions as intrinsic asthma, atopic dermatitis and acute and chronic urticarial eruptions.

Side reactions. Proportionately, nearly twice as many patients had untoward reactions from Benadryl as from Pyribenzamine (Table 2). Some patients noted more than one side effect. The complaint most frequently observed was drowsiness associated with mental sluggishness. Whereas 61 per cent of patients treated with Benadryl were afflicted in this way, only 20 per cent of those treated with Pyribenzamine gave evidence of sedation. Gastrointestinal disturbances, ranging from nausea, anorexia and epigastric distress to vomiting, diarrhea and abdominal colic, were encountered somewhat oftener after Pyribenzamine than after the other drug. A sense of exhaustion and generalized weak-

ness occurred after 8 per cent of the Benadryl treatments, whereas only 3 per cent of patients treated with Pyribenzamine had this type of side effect. Central stimulation caused insomnia and sensations of nervous tension in 4 per cent of both groups. There were 2 cases of headache, both related to Pyribenzamine. Dizziness was reported by 6 per cent of patients given Benadryl and by 3 per cent of those treated with Pyribenzamine. Muscle twitchings, tenderness and aches and in some cases difficulty in phonation and in co-ordinating movements of the extraorbital muscles were described by 6 per cent of the former group and by 2 per cent of the latter. One patient in each series complained of feeling depressed. An occasional case of numbness of the lips and tongue was detected, the con-

dition was ascribed to the local anesthetic action of both drugs. One patient believed that Benadryl provoked a cough lasting for several days, and another was certain that a pre-existing asthmatic cough had been exaggerated shortly after the taking of Pyribenzamine. The former has been listed under the heading of "hypersensitivity" for want of a better classification.

DISCUSSION

There seems little doubt that the histamine antagonists are of definite value in the symptomatic relief of acute urticaria and of seasonal hay fever. Their value in the prevention or control of manifestations due to overdosage with therapeutic allergens is difficult to appraise. If, as in the experiments of Arbesman,² the drug is given shortly before the "overdose," there is always the possibility that on this particular occasion the dose would have been tolerated even without the drug. On the other hand, if one awaits the development of systemic manifestations the drug must be allowed fifteen to twenty minutes for its effect to become apparent. Obviously, such delay would be unwarranted if the situation was at all critical.

One is limited, therefore, to studying the new drugs in cases of relatively mild systemic reaction. Under these circumstances, judgment is clouded by the tendency of mild overdosage reactions to subside spontaneously after twenty or thirty minutes.

Theoretically, it might be expected that such overdosage symptoms as urticaria, hay fever and histamine-like hypotension would be counteracted by the drugs. If bronchospasm developed, however, it would be anticipated that they would prove less effective. Our limited experience with overdosage reactions seems to be in keeping with these theories. It seems probable that the simultaneous administration of adrenalin intramuscularly and of a histamine antagonist orally would ensure prompt relief and sustained control of symptoms other than asthma. In the latter situation it might be wiser to replace the antihistamine drugs with Neo-Synephrin or some similar, orally administered antispasmodic.

Although seasonal hay fever and other extrinsic types of vasomotor rhinitis are symptomatically relieved by the new drugs in a high proportion of trials, the most satisfactory management of hay fever appears to rest on a combination of specific therapy and of symptomatic relief with the antihistaminic agents. Many of the patients came to this conclusion by the end of the 1946 ragweed pollinating season, whether they had omitted their customary "booster" courses and had depended on the drugs alone or had taken injections and employed the drugs only occasionally when necessary. The new drugs play their most valuable role in acute and even in some cases of chronic urticaria because no other satisfactory remedies are available. This remark also applies to such cases of bronchial asthma as respond to Benadryl or Pyribenzamine.

There are important differences in the types and incidences of side reaction that follow the two drugs. Although Benadryl produced sedation in 60 per cent of patients, this fact may be turned to advantage when fatigue, anxiety or insomnia complicates the allergic disorder. The sedative effect is also highly desirable for pruritus. Benadryl should be deliberately selected in such cases. On the other hand, patients whose efficiency and judgment may be impaired by sedation should be given Pyribenzamine for daytime use. Since gastrointestinal complications follow Pyribenzamine some-

what oftener than they do Benadryl, the latter is probably more suitable for patients with abnormalities of gastrointestinal function. It was our impression that the taking of food with Pyribenzamine or of caffeine or benzedrine with Benadryl obviated some of the side effects.

Whereas most patients given first one remedy and then the other reported comparable results with each, a small group responded selectively. It would be well, therefore, to change to the other drug when one gives rise to either undue side reactions or unsatisfactory therapeutic control.

SUMMARY

Among 150 patients given Pyribenzamine and 53 given Benadryl by mouth, partial or complete control of symptoms was noted by over 80 per cent of those with acute urticaria or allergic rhinitis of seasonal (pollen) origin.

Twenty-three of 33 patients treated first with one and later with the other histamine antagonist obtained equal relief with the two. Of the remainder, 5 preferred Benadryl, and 5 Pyribenzamine.

The side effect most frequently encountered with either drug was sedation, which was noted in 61 per cent of cases after Benadryl and in 20 per cent after Pyribenzamine. The second most frequent side reaction was gastrointestinal disturbance, which developed in 10 per cent of the former and 14 per cent of the latter. Central excitation and other untoward reactions, which were of relatively mild intensity and infrequent occurrence, were observed in about the same proportion of both groups.

Administration of the drugs to allergic persons during "constitutional" reactions in 20 cases produced encouraging results for urticaria, hay fever and mild bronchial spasm, but severer asthma seemed to resist their influence.

The technical assistance of Mrs. Gloria Giarrizzo is acknowledged.

ACUTE HEMOLYTIC ANEMIA IN PRIMARY ATYPICAL PNEUMONIA PRODUCED BY EXPOSURE AND CHILLING*

R A COLMERS, M D,† AND J G SNAVELY, M D‡

STAMFORD, CONNECTICUT

ACUTE hemolytic anemia in the course of primary atypical pneumonia has been reported by Dameshek,¹ Finland² and others. Elucidation of the mechanism of this form of anemia has not been offered. Clinical evidence shows that such anemia develops coincidentally with high titers of cold agglutinin in the serum. Since most of these reports have been concerned with patients to whom varying amounts of sulfonamides have been given and since acute hemolytic anemia can develop from the administration of the sulfonamides alone, it has been difficult to exclude the drugs entirely as the cause or to establish the acute hemolytic anemia of primary atypical pneumonia as a separate entity. Ginsberg³ has reported the occurrence of acute hemolytic anemia during the course of primary atypical pneumonia in which no sulfonamide was given.

The patient in the case reported below received no sulfonamide. The clinical and experimental data indicate that exposure and diffuse chilling were instrumental in producing the anemia. These data are in accord with and are an extension of previously known facts. This mechanism has been postulated by Dameshek¹ and Finland² in the reports cited above. Their view was based, at least in part, on evidence that the anemia developed before the administration of sulfonamide and that this therapy did not appear to influence the course of the anemia.

GENERAL CONSIDERATIONS

Increased cold-agglutinin titers in this disease were first described by Clough and Richter⁴ in 1918. Their patient had a diffuse bronchopneumonia with the usual course and with objective findings of what would now be called a primary atypical pneumonia. They failed to associate the disease and the serologic changes and assumed the cold agglutinin to be a peculiar hereditary trait. Cold agglutinin was present in the serum to a titer of 1,500 at refrigerator temperature. The properties of this cold agglutinin were studied with classic thoroughness, and with the exception of the agglutination of indifferent streptococci by Thomas et al.,⁵ little of significance has been added by subsequent studies. Clough and Richter's patient also showed a transient slight depression of the red-cell count and hemoglobin content.

Of particular interest is the report of the inverse relation between the temperature at which the cold-agglutination tests were performed and the degree of agglutination. The titer, which was highest at "ice chest" temperature, became progressively lower at higher temperatures, and agglutination was abolished at 24°C.

In 1926, Li Chen-Pien⁶ reported that cold hemagglutinins found in a patient suffering from cirrhosis and syphilis had similar properties to those in the case reported by Clough and Richter. The inverse temperature effect was demonstrated, and the agglutination was negative at temperatures greater than 20°C. The Donath-Landsteiner test was negative.

In 1939, Wheeler, Gallagher and Stuart⁷ described a potent cold agglutination in a respiratory infection similar to that reported by Clough and Richter. These authors also failed to associate the disease and the serologic changes. A study of the properties of the cold agglutinin agreed with the findings of Clough and Richter. In particular, a similar inverse relation between the temperature and the degree of agglutination was observed. The titer was 1:10,240 at 4°C, 1:2,560 at 12, and 1:160 at 22, and no autohemagglutination was present at 30. This patient did not show anemia.

In 1943, Peterson, Ham and Finland⁸ noted the association of powerful cold agglutinins with primary atypical pneumonia. Similar cases were then reported from other clinics.⁹⁻¹¹ In 1945 Finland and his associates¹¹ published a report of cold-agglutinin titers in primary atypical pneumonia, in common diseases of temperate climate and in health. A study of the properties of the cold agglutination¹² reconfirmed the findings of Clough and Richter.

Observation of the hemolytic properties of the cold agglutinin began with the work of Salen,¹³ who recognized that this hemolysis did not require complement and was therefore quite different from the Donath-Landsteiner hemolysis. Salen demonstrated hemoglobinuria in a subject with powerful cold agglutinins by immersing the legs in ice water. The entire study is difficult to interpret, since Salen did not recognize the role of mechanical trauma in producing hemolysis. His protocol of method calls for thorough mixing of cells and serum by shaking, transferring and centrifuging.

A series of reports by Stata and associates¹⁴⁻¹⁶ presented clear demonstration of the mechanism of hemolysis of erythrocytes in the presence of

†Associate, Department of Medicine, Stamford Hospital.

‡Director, Department of Laboratories, Stamford Hospital.

powerful cold agglutinins Hemolysis was shown to be due to mechanical trauma, such as shaking or tapping, applied to the cold-agglutinated erythrocytes The degree of hemolysis was directly proportional to the heaviness of the cell suspension and the

Thus, the coincidence of the temperatures of cold-agglutinin activity and of the skin may be easily attainable in certain cases
In view of the above considerations, the following clinical record approaches an experimental protocol

degree of agglutination Intravascular cold agglutination was demonstrated in vivo when the tissue was adequately chilled Hemolysis was shown to occur in vivo after such intravascular cold agglutination

For details of the ingenious methods employed by these workers, the reports should be consulted Unfortunately, none of the cases presented evidence of anemia The inverse temperature relation previously noted was present in the most thoroughly studied case, but in spite of high titers at low temperatures, the temperature of extinction of agglutination was 16°C Only small parts of the body of the subject were exposed to temperatures below 16°C either clinically or experimentally This patient had gangrenous changes in the tips of the extremities as the result of activity of cold agglutinins during severe exposure¹⁵

The premise that this mechanism of local hemolysis is the underlying cause of the acute hemolytic anemia associated with powerful cold agglutinins could be tested by reduction of the temperature of a large area of the skin surface and subcutaneous tissue of a suitable human subject to a level at which potent cold agglutinins would be active This degree of cold might be any temperature from 4 to even 37°C, depending on the temperature at which the cold agglutinin was sufficiently high in titer to produce agglutination and lead to subsequent hemolysis Temperature ranges of the exposed skin and subcutaneous tissue depend largely on the room temperature and degree of exposure and are usually from 24 to 34°C After exposure to cold, the skin temperature may fall grossly below this level¹⁷

in which the previous hypothetical conditions for development of acute hemolytic anemia were satisfied

CASE REPORT

A 21-year-old unmarried woman was admitted to the hospital on March 29, 1946, with the chief complaints of malaise, weakness, chills, fever and cough Three days prior to admission the patient had noticed chilliness, fever and generalized aching Two days later a hacking cough pro-

ductive of a small amount of white mucoid material developed There was no history of blood-tinged or rusty sputum or of pleuritic pain
The past history revealed that voluntary dietary restrictions had led to the loss of 20 pounds in the 3 or 4 months prior to admission There was no further clinical history of any significance
Physical examination was negative except for finely crepitant rales in the lower lobe of the left lung posteriorly The temperature was 102.2°F, the pulse 100, and the respirations 22 The blood pressure was 128/78

The clinical diagnosis was primary atypical pneumonia of the lower lobe of the left lung.

Examination of the blood disclosed a red-cell count of 4,100,000 with a hemoglobin of 12.5 gm per 100 cc. and a white-cell count of 9900, with 81 per cent adult neutrophils, 16 per cent small lymphocytes, 2 per cent monocytes and 1 per cent basophils. (The total and differential white-cell counts did not change essentially from admission levels during the first 2 weeks in the hospital.) Urinalysis showed nothing remarkable except on one occasion reported below Table 1 presents the pertinent laboratory data.

Penicillin therapy was begun on the 1st hospital day in doses of 30,000 units every 3 hours but was discontinued after 3 days because it appeared to be of no value. The fever tended to decrease somewhat until April 4, but on the following day there was an upward swing of the temperature with a spiking pattern. Progressive pallor and weakness were observed. The nurse's records reported "dark urine," but these specimens were not saved for examination.

On April 8 the clinical and roentgenologic signs of pneumonia had spread to both lungs. The spleen was enlarged and the hemoglobin had dropped to 7.5 gm per 100 cc., with a red-cell count of 2,070,000 (Table 2) the patient passed swiftly and yet imperceptibly into a serious condition. On the same day the red cells, when mixed with the patient's

at 7 and 26 C increased to 1.5120. In spite of this, no further hemolysis occurred and the patient slowly recovered. Rigid precautions were taken during this period to keep her warm. She was sent home on May 2 with instructions to avoid cold exposure and tub baths.

The temperature chart is presented in Figure 1. The hemolysis *in vitro* is shown in Table 4. The hemolysis is interpreted as due solely to unavoidable trauma to the cells.

Experimental Data

On April 30, after recovery had been assured it seemed safe to perform an experiment. The cold agglutinin titer on that day were 1:2560 at 4°C. and 1:40 at 26, and no agglutination was found at 37.

The right arm was immersed for 15 minutes in ice-cold water containing pieces of ice. The patient voided immediately before the immersion, and this urine was saved for control purposes. A sample of blood was obtained from the left arm immediately before immersion. Every precaution was taken to avert adventitious hemolysis. Blood samples were withdrawn from the right arm 15 minutes after the cessation of immersion (30 minutes after the beginning of immersion). Blood samples were drawn from the same arm at 15-minute intervals thereafter. These blood specimens were labeled 0 (control), 30 minutes, 45 minutes and 60

*Procedure consisted of serial dilutions of serum in physiologic saline solution beginning at 1:5. The total volume of serum in addition to physiologic saline solution was 0.5 cc. To each of the tubes 0.2 cc. of cell suspension was added. As indicated, Type O or adequately washed patient's cells were used. All tubes were incubated overnight, and then the agglutination was dispersed by incubation at 37°C. The serum titers are expressed independently of the further dilution produced by the volume of fluid in which the cells were suspended.

own serum, agglutinated in 10 to 20 seconds at 26°C. The clumping was easily visible on gross inspection and resembled that seen in slide typing with potent agglutinating serum. After eight washings with warm saline solution the red cells no longer agglutinated spontaneously, and blood typing could be done.

Cold-agglutination tests showed a titer of 1:1280. The titer at 26 was identical to that at 7°C. the titer at 37°C. however was only 1.5, and the clumping in the 1.5 dilution was dubious. All agglutination could be dispersed by warming of the tubes to 38°C. (Table 3). During the night the temperature rose to 106°F.

In spite of explicit orders to keep the patient warm a nurse gave her three general body sponges using ice alcohol. On the following morning the red-cell count had dropped to 1,640,000, with a hemoglobin of 4.5 gm per 100 cc. The patient looked moribund. A dark brown urine specimen was reported to have been passed in the morning after the sponges, but had been discarded. The next specimen showed no demonstrable hemoglobin by chemical test.

Between April 9 and 11 a total of 3000 cc. of fresh and banked blood was given. The blood was warmed to 37°C in a water bath before delivery to the bedside and was kept warm during administration. No reaction occurred. The absence of any reaction may have been of some importance, since intracellular hemosiderin granules were demonstrated in epithelial cells obtained from the centrifuged urinary sediment on April 13. Between April 11 and 17 at the suggestion of a consultant, 100,000 units of penicillin was given intramuscularly every 2 hours.

During this period the clinical evidence of pneumonia became more obvious, and the titer of the cold hemagglutinins

minutes respectively. A final specimen was drawn from the same arm 120 minutes after the beginning of exposure. Plans to draw corresponding samples from the left arm had to be abandoned because of residual damage to the veins of this arm as the result of prolonged and intensive intravenous therapy.

After collection of these samples the blood was allowed to clot at room temperature with no agitation. The serum was separated with great care. The warm tubes were then centrifuged to remove any possible residual cells or particulate material. Except for slight difficulty in obtaining the 30-minute specimen (necessitating reposition of the vein), the blood samples appeared to have been ideally obtained. The difficulty with the 30-minute specimen did not appear adequate to account for significant hemolysis *in vitro*.

The patient voided 1½ and 12½ hours after the beginning of immersion of the arm. All the voidings were saved to a dry clean container. After thorough mixing portions of each of these specimens and of the control urine were saved for spectral analysis.

The serum and urine specimens were subjected to spectral analysis* 36 hours after immersion. The 120-minute sample was not tested.

The control and the 120-minute serums were completely free from any trace of hemoglobin on gross visual inspection. The 30-minute specimen was markedly hemolyzed and the 45-minute specimen showed somewhat less marked hemolysis. The 60-minute specimen showed only the faintest trace of hemolysis, and there was a difference of opinion concerning whether this was actually visible.

*Performed on a General Electric recording spectrophotometer in the American Cyanamid Laboratories, Stamford, Connecticut.

The spectral analyses of the serums are presented in Figure 2. The control specimen revealed a faint trace of absorption that seemed insignificant and possibly represented an unavoidable minimum of hemolysis. The 30-minute curve disclosed characteristic spectral absorption bands of oxyhemo-

globin. The 45-minute specimen showed similar absorption bands differing only quantitatively from the preceding specimen. The 60-minute specimen demonstrated the absorption bands of the serum to be markedly reduced and only slightly greater than those of the control serum. This amount of resid-

ence of hemoglobinuria suggests that the systemic hemoglobinemia did not reach a sufficient concentration to appear in the urine and was disposed of by some other mechanism. Within a few minutes after immersion, a peculiar dark purple mottling of the immersed portion of the arm was

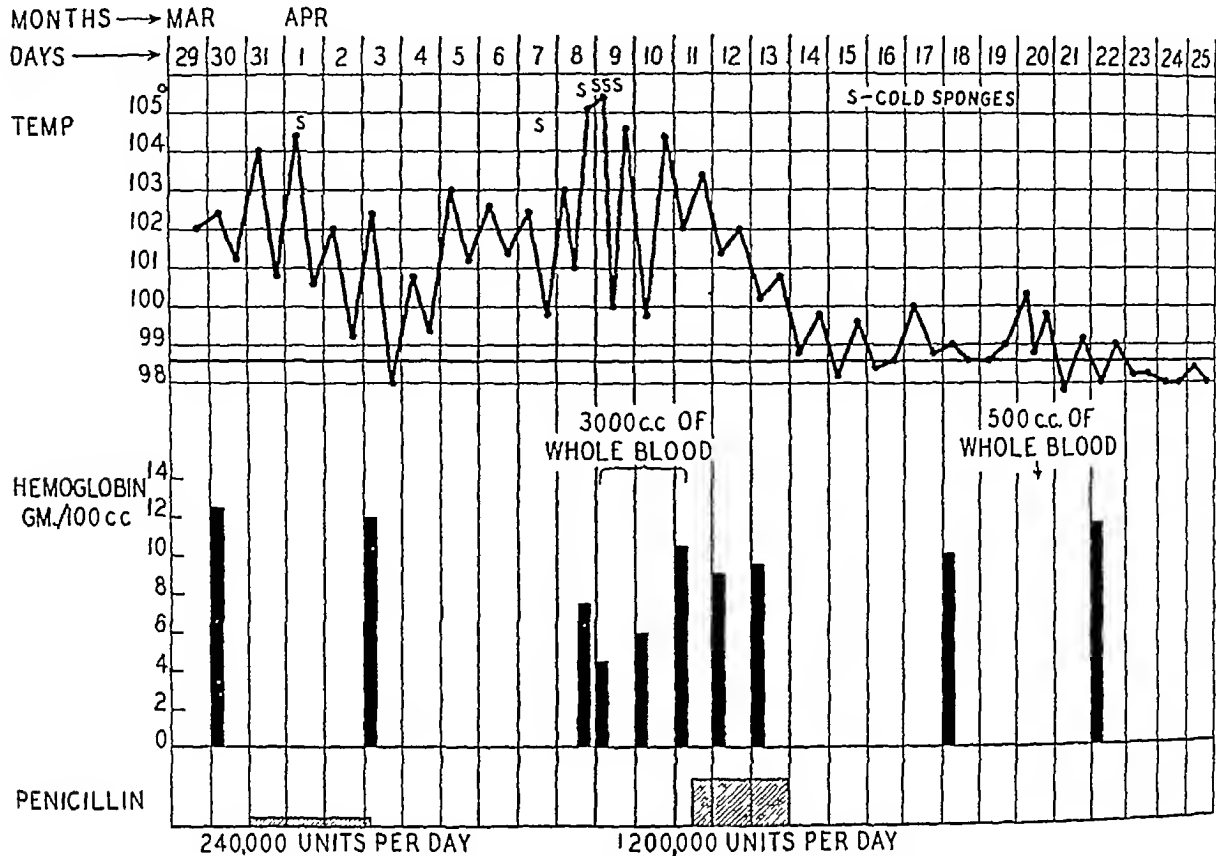

FIGURE 1 Temperature Chart, Hemoglobin Levels and Penicillin Therapy

globin. The 45-minute specimen showed similar absorption bands differing only quantitatively from the preceding specimen. The 60-minute specimen demonstrated the absorption bands of the serum to be markedly reduced and only slightly greater than those of the control serum. This amount of resid-

noticed. Fifteen minutes after removal of the arm from the ice water, this began to disappear, and the skin resumed its normal appearance after 1 hour. The local mottling was thought to be due to reversible intravascular agglutination in the chilled skin and subcutaneous tissue, resulting in ob-

*No hemolysis was more than a slight trace. Except for the duplicate tests with guinea-pig complement this table does not represent separate tests but merely shows hemolysis read in the cold-agglutinin tubes, independent of shaking.

†Duplicate sets of each test with 4 units of guinea-pig complement showed identical titers.

ual hemoglobin seems significant only as showing a nearly complete cessation of the local hemolysis.

The spectral analyses of urine samples are presented in Figure 3. These are marked 0, 1½ hours and 12½ hours, respectively. None of these samples showed any trace of absorption bands in the zones of oxyhemoglobin. The ab-

struction of the lumens of small vessels, which in turn gave rise to local, mottled cyanosis.

DISCUSSION

Cold agglutination of homologous and heterologous erythrocytes has been sporadically reported in

various diseases and much more regularly in association with primary atypical pneumonia. Occasionally, a hemolytic anemia develops in the course of primary atypical pneumonia associated with powerful cold agglutinins in the serum. Confusion of this type of hemolytic anemia with that associated with sulfonamide therapy has been dispelled by the recent report of a case in which no sulfonamide was given.³ There seems to be little reason not to regard the acute hemolytic anemia of primary atypical pneumonia as a distinct entity due directly to the action of cold agglutinins on the red cells of the patient. Intravascular hemolysis by cold agglutinins depends on the trauma suffered by previously agglutinated erythrocytes in their passage through fine blood vessels. The degree of destruction of erythrocytes is proportional to the titer of the agglutinins and the heaviness of the cell suspension.

The production of hemolytic anemia seems to depend on many factors, such as the temperature

convenience in discussing the effect of temperature, an arbitrary term, "temperature hemolysis factor," is introduced. This is defined as the maximum tem-

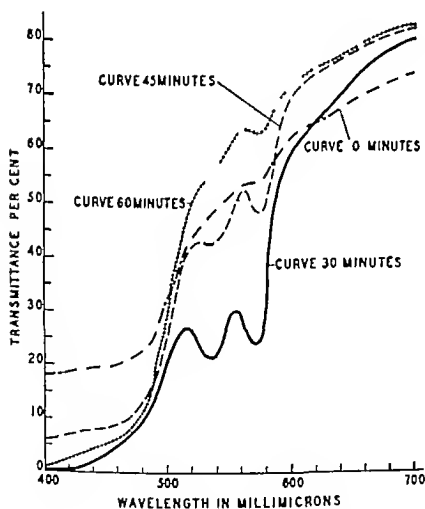

FIGURE 2. Serum Absorption Bands following Chilling

of potent cold-agglutinin activity, the number of red cells destroyed and the duration of exposure. These are considered individually below.

The temperature factor cannot be divorced from the titer of the agglutinins because of their close inverse relation, as shown by other observers.^{4, 5, 7} Since the exact cold-agglutinin titer for production of hemolysis *in vivo* is not known, for the sake of

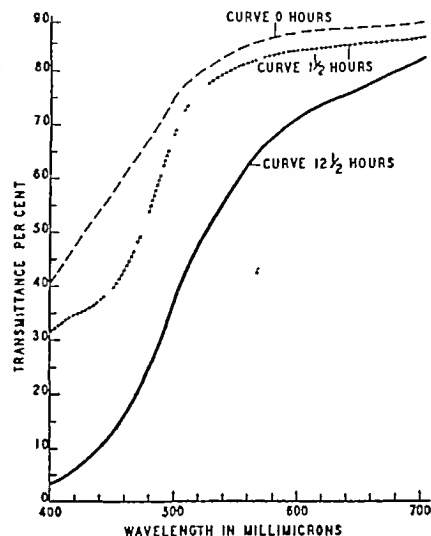

FIGURE 3. Urine Absorption Bands following Chilling

perature at which cold agglutinins are sufficiently active to give intravascular hemolysis. This term is important, since cold agglutination, for the most part, is a phenomenon observed at refrigerator temperatures.⁸

The term "cold" is relative, and cold agglutination has been observed repeatedly at temperatures ranging from 20 to 37°C. These ranges coincide with skin temperatures under conditions of ordinary exposure. When the temperature hemolysis factor and skin temperature coincide, hemolysis must occur.

The temperature to which the skin must be lowered to give hemolysis is directly related to the temperature hemolysis factor of the cold agglutinins. Unusual chilling, as in the case presented above, may be necessary for hemolysis if the temperature hemolysis factor is low, but not necessarily if the factor is sufficiently high.

More hemolysis does not lead to anemia unless a sufficient quantity of erythrocytes are destroyed.

*In the experience of one of us (J. G. S.) 20 cases of elevated cold agglutinin titers have been studied. The case presented above is the only one in which activity at 26°C. could be demonstrated and in which hemolytic anemia was present. The titers at 7°C. in these cases ranged from 1:160 to 1:5120 (expressed in terms of dilution of serum).

This quantity must be related to the volume of tissue exposed and the duration of exposure. We have no evidence on which to base any estimation of the proportionate, quantitative effect of these factors.

The production of acute hemolytic anemia thus depends on the coincidence of a number of variables of uncertain proportionate importance. Under such circumstances a dramatic episode may be needed to call attention to the precipitating factor or factors. In the case reported above, a marked anemia developed without much hint of its cause until the overnight drop of 40 per cent in the hemoglobin following severe chilling literally forced this factor to our attention.

A few points of the clinical record need clarification. One of these is the absence of proof of hemoglobinuria. The nurse's observations clearly pointed to this, but objective proof was lacking, owing to the inadvertent discarding of the urine samples. Neither was there clinical evidence of jaundice, although there was a slight elevation of the total serum bilirubin. The objective proof of the destruction of red cells rested largely on the red-cell counts, hemoglobin determinations and clinical observations. Since the counts in relation to corresponding blood hemoglobin contents fell within the expected range of error, fallaciously low counts due to intrapipette hemolysis or other technical errors seem to have been eliminated.

Furthermore, all the counts except the first two were mean values obtained from multiple determinations in which warm diluent, warm pipettes, shaken at incubator temperature, and warm hemocytometers were used to avoid such difficulties. The total change in the counts was too large and too rapid to be accounted for in any other way than by intravascular hemolysis or massive hemorrhage. There was nothing to suggest a hemorrhage of such magnitude.

To explain the absence of jaundice, the mode of disposal of the released hemoglobin is of prime importance. Destruction of the same number of red cells in other conditions usually results in marked bilirubinemia and clinical jaundice. We are forced to assume that a large portion of the hemoglobin was disposed of in the urine in this case. There appears to have been a difference between the mode of disposal of intravascularly released hemoglobin and the extravascular destruction of red cells. This hypothesis is under investigation. Intracellular hemosiderin granules in the cells of the urine sediment, in the absence of transfusion reaction, suggested renal disposal of the hemoglobin.

SUMMARY

A case of primary atypical pneumonia in which potent cold agglutinins resulted in an acute hemolytic anemia in the absence of sulfonamide medica-

tion is presented. At the time of the development of maximum anemia, cold agglutination was present in the serum with identical titers at 25 and 7°C. At that time a trace of agglutination was even present at 37°C. The anemia developed coincidentally with the administration of cold alcohol sponges and exposure.

With recognition of the cause of hemolysis, further, and possibly fatal, hemolysis was prevented by rigid precautions against chilling, in spite of even higher titers of agglutinins found later in the disease.

A mechanism of local hemolysis was demonstrated experimentally, confirming the findings of Stats and his associates.

The temperature factor of the cold agglutinin activity is just as important as the level of cold agglutination at 7°C. The cold-agglutination test should be done routinely in triplicate racks incubated at 7, 26 and 37°C. Although an arbitrary level cannot be given, any appreciable titer of cold agglutinins at or above 26°C should probably be considered potentially dangerous.

Acute hemolytic anemia due to the mechanism demonstrated should be avoidable.

Since cold sponges, administration of antipyretic drugs and ordinary exposure are routine procedures in the treatment of febrile patients, the significance of these factors in the production of acute hemolytic anemia in primary atypical pneumonia may easily be overlooked. Alertness to these factors in future cases may make it possible to evaluate the general application of the case reported.

This appears to be the only case of hemolytic anemia in primary atypical pneumonia in which a mechanism of hemolysis has been elucidated. The hypothesis is strongly supported by clinical and experimental data.

PREFRONTAL LOBOTOMY IN THE CHRONIC DEPRESSIVE STATES OF OLD AGE

ABRAHAM MYERSON, M.D.,* AND PAUL G. MYERSON, M.D.†

BOSTON

THE operation known as prefrontal lobotomy was first performed by Moniz¹ in 1936. Since that time, the procedure has been widely employed in many types of mental illness in which the course of the disease has been prolonged and the outlook desperate. The operation consists of the cutting of a part of the fibers between the thalamus and prefrontal lobes.^{2,3} The rationale has been to disassociate, by surgical means, pathologic thinking from its emotional reverberation. This, of course, is a vast oversimplification of an extremely complex psychologic and neurophysiologic event. The results, when successful, have relieved patients of overwhelming anxiety, obsessive thinking, depression and other crippling emotional reactions. The best results have been obtained in chronic depressions and in some obsessive-compulsive states in which there is marked anxiety. It has been the experience of most observers that the results in chronic schizophrenia are far from satisfactory.

Mental illness in old age is usually regarded as a hopeless problem. The physician has an attitude of therapeutic nihilism and, as a rule, tends to classify all syndromes as organic and to emphasize the deteriorating aspects of senility. The realities of old age, as well as the lack of physical and mental resiliency, make most types of therapy extremely difficult, even when it is recognized that the essential features of the psychosis are those of a depression. It is a frequent clinical experience that such patients react poorly to electric shock therapy. For this reason, the following case histories of 4 women, over sixty years of age, with chronic depressions whose symptoms were greatly alleviated by means of prefrontal lobotomy are reported.

CASE 1. The patient was a 73-year-old woman whose family history was replete with mental illness. A daughter had recurrent manic-depressive episodes, a son had a severe anxiety state and there was a strong familial history of mental illness in the patient's siblings and collateral relations. The family described her as a sensitive person who

tended to worry over details. On the whole however she got along with her friends and showed no mental abnormalities until the age of 63. The depressive episodes, at first, lasted only a few months and usually occurred in the spring.

In 1944 the patient began to feel depressed in the winter, when she was first seen by us. She was quite depressed and extremely agitated and hypochondriasis was marked. In April 1945 she was sent to an institution where she remained for several months without any improvement. Finally, her condition became so marked that she was given electric shock treatment in October, despite her advanced age and in the presence of auricular fibrillations. She again received electric-shock therapy in November and December without improvement.

Because of the pronounced agitation and intractable depression a prefrontal lobotomy was performed on December 22 by Dr. James L. Poppen. Almost immediately the patient's mood improved. There was some difficulty in control of the bladder for about 4 weeks. During the 3rd postoperative week she was playing bridge. Subsequently, she was relaxed, and there was no recurrence of the depression or agitation. She carried on her household duties as before and she was quite capable of meeting people adequately. There was no obvious change from the level of intellectual abilities that she had maintained prior to operation. So far as the family was concerned, there was no change in personality or temperament, and she was much more agreeable to live with than at any time in many years. When last seen she was pleasant, courteous and alert and gave every evidence of being a reasonably content elderly woman who was aging in a satisfactory fashion.

CASE 2. This patient, a 62-year-old woman had a sister who had been in a mental institution for many years because of a chronic depressed state. Throughout her life, the patient had bad occasional episodes of depression usually lasting several months at a time and associated with strong feelings of hopelessness and marked somatic disturbance. She was first seen in May 1944 when she had been severely depressed for 10 months. She was given four electric-shock treatments with partial recovery and in October of the same year she was given five more. Subsequently she did quite well for a year when there was a recurrence of depression for which she received seven electric shocks. She showed only temporary improvement, and shortly thereafter the depression and agitation recurred. She was unable to sleep and lost considerable weight because she refused to eat.

In January 1946, a prefrontal lobotomy was performed by Dr. Poppen. Almost immediately the patient became cheerful, and within several months she had gone back to managing her household. This improvement has continued until the present time. The husband stated that she had been uniformly happy and untroubled. When unusually tired she seemed quieter than formerly, but never depressed and readily recovered from the fatigue. She was entirely capable of controlling the family budget, planning her work, shopping and so forth. She enjoyed meeting people—even pourne at a faculty tea. Her intellectual capacity was no different from that in the past. Friends told the husband that in the 20 years they had known the patient, she had never seemed so well and so normal. He could detect no personality

*Professor of neurology, emeritus, Tufts College Medical School for formerly clinical professor of psychiatry Harvard Medical School director of research, Boston State Hospital.

changes except the absence of fear. Occasionally, she seemed somewhat detached and showed a slight loss of initiative, but these episodes were so slight as to be scarcely worthy of mention. The really significant thing was that she was able to meet greatly increased responsibilities better than for a long time.

CASE 3 A 67-year-old woman was first seen in January, 1942. Her family history was strongly positive for manic-depressive psychosis. A brother had committed suicide, and a sister had had several admissions to a state hospital. The patient had had at least six episodes of mental disease during the previous 10 years. The periods consisted of overactivity lasting several months, associated with euphoria, and were followed by periods of exhaustion, depression and loss of energy. As the years went on, the attacks became more prolonged, and the depression more pronounced. Freedom from symptoms was of brief duration. As in the other cases, there was no delusional formation, no sense of guilt and no retardation. Chiefly, there was a feeling of depression and an absence of energy, drive and interest.

During the next 4 years, the patient was seen during four episodes, in each of which the depressions were terminated by electric-shock treatment until the last attack, which remained intractable to shock therapy, the patient had no remission, remaining completely depressed for 7 months prior to prefrontal lobotomy.

The operation was performed in April, 1946, by Dr. Poppen. The patient's mood changed almost immediately, and she was subsequently pleasant and relaxed. There was no return of depression, but from time to time she complained of a sense of fatigue and weariness. It appears almost that the deep affective disturbance of depression had been altered by the operation in some manner, so that it was experienced as a considerably more endurable reaction. The patient met people well, and intellectually she seemed normal. On the whole, the operation was extremely successful.

CASE 4 A 53-year-old woman was first seen in 1937, when she had been depressed for over a year. There was a history of two previous episodes, the first occurring in the third decade, the other in the fifth. During these attacks, she was depressed, had marked insomnia and anorexia, lacked endurance and was extremely agitated. There were no delusions, feelings of guilt or paranoid trends. She was next seen in 1942. In the interval, she had been in a mental institution, where she was given electric-shock treatment. She improved for a short while, but rapidly slipped back into the previous condition. In 1946 the patient was seen again, and in view of the fact that the depression had lasted in an unmitigated fashion for 10 years despite electric-shock and other treatment, it was decided that prefrontal lobotomy was urgently indicated.

In July of that year, the operation was performed. The patient was quite confused for several weeks after the operation, but then began to show definite signs of improvement. Subsequently, she functioned at a much higher level than previously. She visited friends and did some shopping and entertaining at home for the first time in almost a decade. She herself stated that she had periods in which she felt rather low and lacked energy, but this was not obvious to her family, and in general she behaved in a more socially adequate fashion. There was no impairment of intelligence or judgment.

The cases described above have several features in common. First of all, the patients were all women in the declining years of life who had been mentally ill for years. Secondly, the clinical syndromes were similar. The outstanding features were depression, lack of energy and enthusiasm and retreat on the basis of an overwhelming disturbance in the affect of the patient. In none of these cases was there marked retardation of speech or strong suicidal drives, and paranoid or guilt reactions were not apparent. Thirdly, they all responded remarkably to prefrontal lobotomy. In each case there was a radical improvement both in the way the patient herself felt and in the manner in which she behaved. This resulted in a marked alleviation of the tension and distress that are pronounced in the depressed states. In no case was there obvious intellectual impairment. Of course, none of these women had led an intellectual life in the past, nor had they held positions of responsibility, but judging by past performances — the ultimate criterion — they behaved in a far more useful and socially adequate fashion after the operation. The operation in each case relieved the patient of depression in a striking manner. In at least 1 case, however, a definite sense of fatigue remained, possibly owing to the same factors that were responsible for the depression, but with the severance of the cortico-thalamic pathways, the process is experienced as fatigue rather than as a deeply lowered mood.

The point that is especially emphasized is that old people with chronic depressions should not be regarded as hopeless and doomed to live out their remaining years in retreat and unhappiness. Properly performed, prefrontal lobotomy can do them no harm. We have, as yet, experienced no failures, and it should be emphasized that only cases in which at least a year had elapsed since the operation are reported. The alternative to the operation is to add the misery of melancholia to the disabilities of old age.

MALIGNANT TESTICULAR NEOPLASMS IN INFANCY*

Report of a Case with Six-Year Survival

ADOLPH MELTZER, M.D.,† AND BERNARD BLOOM, M.D.‡

BOSTON

MALIGNANT tumors of the testicle in children are rare. Dargeon,¹ reviewing malignant tumors in 1557 children collected from five major sources, found 211 cases involving the genitourinary tract. Matassarin² quotes Gilbert, who collected 5500 cases of all tumors of the testicle reported in detail from 1803 to 1942 and observed only 131 cases in children under fifteen years of age.

There are several reports of testicular neoplasm in children in the early literature.³⁻⁵ These have been responsible for the frequently quoted opinion that "there have been numerous reports of malignant tumors, usually teratomas in the newborn."⁶ Wells,⁶ however, in a classic article on congenital malignant neoplasms, pointed to the lack of actual proof that the testicle is the seat of congenital cancer. He mentioned several doubtful cases from the early literature and concluded as follows:

No more recent reports [after 1900] can be found indicating congenital or even early infantile malignant growth in the testicle, which makes all earlier reports even more doubtful. Of 100 malignant testicular tumors reviewed by Tanner (1922) only one occurred before the seventeenth year. In a review of malignant disease of the testicle Dew (1926) mentioned only two cases in infants.

It is worthy of note that only four histologic reports of malignant testicular tumors in infants could be found. Two of these are cited by Wells,⁶ as follows:

A typical case is that of Philipp in which the testicle was enlarged at birth. Not until traumatized in the third year did it grow rapidly and on removal, sarcomatous degeneration of a growth diagnosed as teratoma was found. MacLennan also reported a case in which enlargement of the testicle was present at birth with resection at the eleventh month, followed by development of metastases in abdominal and cervical glands and death in two weeks. Histologically it was considered to be adenocarcinoma.

The recent literature provided two additional case reports, one of which describes a seven-month-old infant with enlargement of the left testicle noted one month prior to treatment.⁷ The patient was treated by simple orchidectomy and postoperative radiation and was reported living and well after a follow up study of four and a half months. The diagnosis was embryonal adenocarcinoma. Another case was noted three days after birth in the right

testicle.⁷ Orchidectomy was performed, and a diagnosis of Wolffian epithelioma was made. The authors report the case as unique in the literature of Argentina. The diagnosis in the last case might well correspond with that of the two preceding cases.

The following case of adenocarcinoma of the testis is considered worthy of report because of the rarity of the neoplasm so early in infancy and because of the long follow-up period with apparent cure.

A S (BIH 54467) an 8 month-old boy was admitted to the hospital on September 4, 1940, because of a swelling of the right testicle. The infant had been born after a full-

FIGURE 1 Photograph of the Scrotum on Admission

term normal delivery. At birth the child showed no signs of injury and weighed 9 pounds. At an early age the scrotum was noted to be somewhat larger than normal but both testicles were felt to be of normal size within the scrotum. An attempt was made at the time of the first visit to the Tumor Clinic on October 8 to obtain specific information on this point. The mother stated that she had noted an

‡Assistant in genitourinary surgery, Harvard Medical School; resident in urology, Beth Israel Hospital.

enlargement in the scrotum immediately after the child's birth. This was pointed out to the family physician during the course of an examination at the age of 1 month, but he did not consider that there was anything abnormal in the scrotum. At 4 months a mass was noted in the scrotum. A physician was consulted at that time and called it a hydrocele, deciding that no treatment was indicated. Since a brother of the patient had had a similar swelling, which had been called a hydrocele and disappeared at the age of 15 months, the mother had accepted this advice with confidence and had not hastened to consult a physician again. The swelling of the right testicle felt alternately hard and soft but was never reducible. It had not grown much in size since it had first been noted but had become consistently harder. The child had gained normally in weight, the weight on admission being 23 pounds. No signs other than the scrotal mass had been noted. On August 30 the mother had

tion of the urinary sediment revealed occasional white cell and 1 or 2 red cells per high-power field, but no casts. The Aschheim-Zondek test was negative.

X-ray examination of the lungs was negative. There was no evidence of metastatic lesions in the shoulders, ribs, dorsolumbar spine, pelvis and hips. X-ray study of the scrotum revealed a large soft-tissue mass in the right testicular region in which no calcification was noted.

On September 12 a right orchidectomy was performed with ligation and transection of the spermatic cord at the level of the external inguinal ring. No hydrocele was present.

Gross pathological examination disclosed that the tumor weighed 49 gm and measured 5.5 by 4.5 by 4.0 cm (Fig. 2). It appeared completely encapsulated by reddish-tan fibrous tissue. The tumor mass occupied most of the submitted specimen, and was covered by a thin, glistening tan membrane. There was no gross evidence of remaining testicular

FIGURE 2 Photograph of the Tumor on Section, Showing Gelatinous Appearance and Areas of Hemorrhage, Necrosis and Cystic Change

again consulted a physician, who had advised admission to a hospital.

Physical examination revealed a chubby, somewhat pale child. The skin was normal. Abdominal examination revealed no masses. No inguinal lymphadenopathy was noted. The penis had been circumcized. The scrotum was considerably enlarged and tense (Fig. 1), but the overlying skin was not reddened, edematous or warm. Palpation revealed the left testicle to be normal in size and consistence. It was pushed far over to the left by a large mass in the region of the right testicle. The right testicle could not be discerned. In the right side of the scrotum there was an egg-shaped mass measuring about 6 cm in its greatest diameter. The mass seemed tense rather than hard in consistence. Its surface was smooth. There were no masses in the inguinal canal. The mass did not transilluminate light. No impulse was transmitted when the child cried or coughed. The overlying skin was freely movable. The mass could not be reduced or displaced toward the inguinal region. The perineum was normal. Rectal examination was not done.

Examination of the blood disclosed a red-cell count of 4,640,000, with a hemoglobin of 80 per cent, and a white-cell count of 7400, with a normal differential count. Examination

of the urinary sediment revealed occasional white cell and 1 or 2 red cells per high-power field, but no casts. The Aschheim-Zondek test was negative. X-ray examination of the lungs was negative. There was no evidence of metastatic lesions in the shoulders, ribs, dorsolumbar spine, pelvis and hips. X-ray study of the scrotum revealed a large soft-tissue mass in the right testicular region in which no calcification was noted.

On September 12 a right orchidectomy was performed with ligation and transection of the spermatic cord at the level of the external inguinal ring. No hydrocele was present. Gross pathological examination disclosed that the tumor weighed 49 gm and measured 5.5 by 4.5 by 4.0 cm (Fig. 2). It appeared completely encapsulated by reddish-tan fibrous tissue. The tumor mass occupied most of the submitted specimen, and was covered by a thin, glistening tan membrane. There was no gross evidence of remaining testicular tissue. The cut surface of the tumor presented a variegated appearance. Most of the tissue was a brilliant yellowish brown, but it was mottled by reddish-brown hemorrhagic areas and by red necrotic patches. The tumor tissue bulged above the cut edge of the capsule and was edematous; it was soft in consistence, but not uniformly so. Numerous small cystic areas filled with a colorless gelatinous material were seen, but the cut surface as a whole had a gelatinous texture. Microscopic examination of six sections revealed an essentially uniform picture of a neoplasm that was pleomorphic and undifferentiated. The neoplastic cells were variable in shape, size and staining reaction. The predominant cell type was characterized by a large, round, vesicular nucleus containing coarse clumps of chromatin; this type of nucleus was surrounded by pale-staining cytoplasm that frequently exhibited vacuolization. The other neoplastic cells were anaplastic variations of this predominant cell type. The neoplastic cells grew in the form of masses, cords and strands. Abortive acinus formation was also present in some areas. The cells forming the abortive acini were hyperchromatic. Numerous mitotic figures were found among the neoplastic cells. The stroma of the tumor itself varied from scanty and tenuous to abundant and dense in different areas.

In the areas where it was scanty the stroma appeared loose, wavy and myxomatous and the neoplastic cells were well preserved. In other areas the stroma was necrotic and contained degenerating neoplastic cells. In a few places complete necrosis to acidophilic amorphous debris was present. A few focal hemorrhagic areas were also encountered. Necrosis and hemorrhage were less frequent to the compact cellular areas of neoplastic tissue where the cells were fairly well preserved and where attempted acinus formation was present. The tumor was surrounded by a thick fibrous capsule which contained remnants of both flattened and well preserved seminiferous tubules. The capsule was slightly invaded by neoplastic cells, and these areas of invasion exhibited infiltration by chronic inflammatory cells at the growing edge of the tumor. The large vacuolated cells seen in the tumor suggested embryoma but the attempted acinus formation suggested carcinoma of the testis. The diagnosis was adenocarcinoma of the right testis.

The postoperative course was uneventful. Healing occurred by primary union and the patient was discharged on the 12th postoperative day in excellent condition.

The patient was followed in both the Tumor Clinic and the Genitourinary Clinic. Radiation therapy was not given. The child developed normally, both physically and mentally. Five months postoperatively examination revealed several firm discrete, freely movable lymph nodes in the right groin and a few smaller ones in the left. This was considered to be secondary to mild penile irritation. In January, 1942 and again in January, 1947, x ray study of the chest disclosed no evidence of metastatic disease. Intravenous pyelography on the latter occasion was likewise negative. The child was alive and well when last seen in January, 1947. It was noted that the inguinal lymph nodes had not changed in size during a 6-year period of observation. He appeared to be somewhat smaller than other children of his age.

although x ray studies of the long and flat bones revealed no retardation to bony growth.

SUMMARY

A case of malignant testicular tumor in an infant is reported. This appears to be one of the few authenticated case reports of malignant testicular neoplasm occurring in the early months of infancy. Another interesting feature of this case is the six-year survival period, with apparent cure. For a tumor characterized by such a high grade of malignancy and rapid growth in the first years of life, this long survival period is noteworthy. It represents the only reported five-year survival of an infant with a malignant testicular neoplasm.

MEDICAL PROGRESS

SERUM LIPIDS AND THEIR VALUE IN DIAGNOSIS*

SIEGFRIED J. THANNHAUSER, M.D.†

BOSTON

THE serum and the lymph fluid not only are the transport medium for all substances absorbed in the intestines but also contain substances that have originated as a result of intermediary and cellular metabolism. It may therefore be assumed that lipids found in the cells of the organs should also be present in the serum. Such an assumption corresponds only partly with the actual analytical findings. The concentration of certain lipids, although fairly high in the cells of organs, is so low in the serum, and the amount at the disposal of chemists working in the clinical laboratory so small, that present methods are not sensitive enough for their determination.

The lipids important for human physiology and pathology are classified as follows:

Saturated fat: glycerol esters of various saturated and unsaturated fatty acids.

*From the Research Laboratory of the Boston Dispensary and the Joseph H. Pratt Diagnostic Hospital and the Department of Medicine Tufts College Medical School.

This study was aided by grants from the Rockefeller Foundation the Godfrey M. Hays Trust Fund and the Charlotte Fund.

†Professor of clinical medicine, Tufts College Medical School, associate chief, Boston Dispensary and Joseph H. Pratt Diagnostic Hospital.

Monooaminophosphatides: fatty acid esters of a phosphorylated polyvalent alcohol, combined with a nitrogen-containing group. Their phosphorus-nitrogen ratio is 1:1. (Some monooaminophosphatides contain other organic groups in addition to those already mentioned.)

Leucithins: phosphoric acid diesters of diglycerides and choline.

Lysoleucithins: phosphoric acid diesters of saturated monoglycerides and choline.

Cephalins: contain their total nitrogen in form of a primary amino group (ethanolamine or serine).

Phosphatidyl ethanolamines: phosphoric acid diesters of diglyceride and ethanolamine.

Phosphatidyl serines: hydrolysis products — fatty acids phosphoric acid, polyvalent alcohols, serine.

Plasmalogens (acetalphosphatides): phosphoric acid diesters of a higher fatty aldehyde acetal of glycerol and of ethanolamine.

Inositol phosphatides: obtained from brain, soybeans and bacteria.

Phosphatide acids (cardiolipins): hydrolysis products — fatty acids, polyvalent alcohols, phosphoric acids (bonded as a monoester).

Phosphatides of acid fast bacteria: hydrolysis products — phosphoric acids, polyhydroxy compounds (such as inositol), fatty acids with straight and branched chains.

Diaminophosphatides (sphingomyelins): acid amide of sphingosine with fatty acids (ceramides) in ester linkage with phosphorylcholine.

Cerebrosides: acid amides of fatty acids with sphingosine or dihydroxyphingosine in glucosidic linkage with galactose or glucose.

- Sulfuric acid esters derived from cerebrosides
- Gangliosides structure unknown, hydrolysis products — sphingosine, neuraminic acid, fatty acids and galactose or glucose.
- Sterols
 - Cholesterol and its esters derived from animal tissues
 - Cholesterol and its esters derived from plants
 - Hydrocholesterols
 - Vitamin D
 - Steroid sex hormones
 - Bile acids

To facilitate an understanding of the roles of the lipids in human disease it appears necessary to discuss the clinical physiology of lipid metabolism

* * *
NEUTRAL FAT

Hyperlipemia — that is, the increase of neutral fat in the serum — is visible to the naked eye because

however, there is no hyperlipemia It should be emphasized that for the routine analysis of blood for neutral fat, the patient should always be examined in a fasting state

Retention Hyperlipemia

Hyperlipemia may be caused by a sluggish removal of neutral fat from the blood stream into the fat depots and into the organs that metabolize fat. The mechanism of such a disorder is not clear at present It may be a neuroregulatory dysfunction or an anatomic change in the wall of the capillaries from which the neutral fat passes into the tissue spaces This form of retention hyperlipemia is relatively rare, and its clinical designation is "idiopathic hyperlipemia" It may occur as an inherited disorder,²⁻⁵ or it may occasionally be observed in

TABLE 1 Lipid Partition of Serums and Liver in a Case of Idiopathic Hyperlipemia*

LIPID	RANGE FOR NORMAL LIVER	LIVER IN IDIOPATHIC HYPERLIPEMIA	RANGE FOR NORMAL SERUM	SERUM IN IDIOPATHIC HYPERLIPEMIA
	gm /100 gm	gm /100 gm	mg /100 gm	mg /100 gm
Total cholesterol	2.1 - 2.6	2.52	150-260	379
Free cholesterol	0.44- 0.55	0.73	40- 70	158
Cholesterol esters	1.50- 2.15	1.79	70- 75*	60*
Total phospholipid	9.0 -11.0	10.05	150-250	465
Sphingomyelin	0.3 - 0.5	1.44	10- 30	13
Cephalin	3.0 - 5.5	3.05	0- 30	Traces
Lecithin	3.0 - 6.0	5.56	100-200	452
Total fatty acid	8.6 -13.0	9.45	200-450	1115
Neutral fat†	1.4 - 4.0	1.22	0-150	2740

*Percentage of total cholesterol
†In idiopathic hyperlipemia the neutral fat is extremely high in the serum but in the range of normal in the liver

the serum loses its transparency and becomes milky or even creamy in appearance It should be emphasized that an increase of cholesterol or phospholipids without an increase of neutral fat never causes a milky serum The designation "hyperlipemia" should be exclusively reserved for an abnormal increase of neutral fat in the serum, whereas the terms "hyperlecithemia" and "hypercholesterolemia" should be used to designate the increase of these respective lipids in the serum Hyperlipemia is usually accompanied by hypercholesterolemia and hyperlecithemia, whereas hypercholesterolemia and hyperlecithemia occur without hyperlipemia in essential xanthomatosis of the hypercholesteremic type, as well as in xanthomatous biliary cirrhosis, as pointed out below

single cases with and without secondary eruptions of skin xanthomas The lipid partition in a typical case is given in Table 1 Since slight glycosuria is present in some cases, the diabetes was formerly considered the causative factor of the hyperlipemia In these cases, however, the hyperlipemia, as well as the glycosuria, disappears after the patient has been given a diet low in neutral fat^{5a} Insulin in these cases has no effect on the hyperlipemia Idiopathic hyperlipemia with hepatosplenomegaly and secondary xanthomatosis of the Bürger-Grütz type also probably belong to this group.^{6 7}

Transportation Hyperlipemia

Hyperlipemia may occur as the result of an increased rate of transportation from the fat depots to the tissues The classic example of this type of transportation hyperlipemia is observed in untreated, severe diabetes mellitus The hyperlipemia in untreated severe diabetes disappears with insulin treatment but does not respond to a diet low in neutral fat It is essential to distinguish patients with severe diabetes and transportation hyperlipemia⁸ from those with idiopathic hyperlipemia and slight diabetes, because of the difference in

Postprandial Hyperlipemia

This is a physiologic occurrence after the intake of a fatty meal The peak is observed within three to five hours Formerly, it was erroneously believed that hyperlipemia is found in obese people On occasions postprandial hyperlipemia may persist for an unusually long period in obese persons If the serum is examined in the postabsorptive state,

treatment. The former are severely sick, and in the latter, who seem to be healthy, the hyperlipemia is accidentally observed because of acute xanthomatous eruptions. The hyperlipemia observed in chronic pancreatitis,¹⁰⁻¹² as well as in glycogen-storage disease (von Gierke's disease),¹³⁻¹⁶ is also considered to be the result of an increased rate of transportation from the fat depots to the organs that metabolize fats.

The mechanism of hyperlipemia and hypercholesterolemia observed in nephrotic conditions, such as lipid nephrosis, the nephrotic state of glomerulonephritis and renal-vein thrombosis, is at present not definitely clarified. It may be assumed that an increased rate of fat transportation also plays a part in these conditions.¹⁴⁻¹⁸

PHOSPHATIDES

The functions of the phosphatides in the organism, so far as they are known, may be distinguished as those pertaining to the intracellular metabolism and those playing a part in the transport of fatty acids. The monoaminophosphatides important for the transport of fatty acids are the lecithins, whereas the cephalins and sphingomyelins are found and retained mainly within the cells. The concentration of the latter in the serum is therefore low. In determining the total phospholipids of the serum 70 to 90 per cent may therefore be evaluated as lecithin. The significance of the lecithins in the transportation of fatty acids was shown by Sinclair and his co-workers¹⁹⁻²² and by Artom and his associates.²³⁻²⁶ An intermediary of lecithin metabolism, glycerylphosphorylcholine, was isolated by Schmidt, Hershtman and Thannhauser.²⁵ The occurrence of this substance in the intestinal mucosa provides a simple explanation for the rapid incorporation of ingested fatty acids into the phosphatide fraction.¹⁹⁻²² The formation of glycerylphosphorylcholine from lecithin is effected by the action of a specific intracellular enzyme, lecitholipase.²⁵

The liver is the main organ for phospholipid synthesis. Fishler, Entenman and Chaikoff,²⁷ using radioactive phosphorus, furnished strong evidence that the liver is the main site of plasma phospholipid (lecithin) formation. Hepatectomized dogs, receiving radioactive sodium phosphate intraperitoneally, showed only minute amounts of radioactive plasma phospholipids six hours after its injection, in contrast to control animals. Despite their reduced ability to form plasma phosphatides (lecithin), the hepatectomized animals were capable of synthesizing phosphatides at a normal rate in the kidneys and intestines.

Choline and cholamine are present in the monoaminophosphatide molecule. The lipotropic effect of choline and its precursors on the fatty livers of choline-deficient rats and of depancreatized animals has been demonstrated by various authors.²⁷⁻²⁹ The amounts of phospholipids, especially those con-

taining choline, are considerably reduced in choline-deficient rats.

It is, however, not proved whether choline or its precursors, the phospholipids, have any curative effect on fatty livers of heterogeneous etiology in human beings. The results of experiments on rats are not necessarily in conformity with bedside experience. The concentration of phospholipids in the serum is not diminished in patients with fatty livers from various causes.

The acetalphosphatides were first discovered by Feulgen³⁰⁻³¹ in the cytoplasm of cells of all tissues and designated as plasmalogens. Although their function is unknown, their structural relation to cephalin gives a hint of their significance in the intracellular metabolism. No attempts have been made to isolate and determine this group of substances in the serum of human beings.

The concentration of cephalins and sphingomyelins in the serum, in contrast to the lecithins, is low and varies only slightly in healthy persons. These lipids are metabolized mainly within the cells, where they are formed. If changes occur in the total phospholipid concentration in the serum, they should be evaluated for their lecithin component.

In Niemann-Pick disease the concentration of sphingomyelin increases enormously in all organs with the exception of the brain. The serum of patients with Niemann-Pick disease, however, does not contain more sphingomyelin than that of normal subjects. The sphingomyelin is apparently retained in the cells where it is formed.³²⁻³⁴ An analysis of the lipid content of the organs, serum and ascitic fluid in Niemann-Pick disease is presented in Table 2.

CEREBROSIDES

The cerebroside is an intracellular lipid. These substances are found in substantial quantities in normal brain tissue, where they are present as galactosidocerebroside ranging from 40 to 60 per cent of dried tissue. The amount of cerebroside in normal visceral organs is minute (0.1 to 0.6 per cent). Klenk³⁵ reported galactosidocerebroside, as well as glucosidocerebroside, in normal visceral organs. Both substances are determined quantitatively by the method of Ottenstein, Schmidt and Thannhauser,³⁷ in which small but measurable quantities of galactosidocerebroside are found in normal visceral organs, whereas glucosidocerebroside is found only in traces.

Carter, working on the lipid fraction of several hundred liters of serum provided by the plasma studies of Cohn and his group during the war, was able to isolate and identify minute amounts (approximately 100 mg.) of cerebroside from 200 liters of plasma.³⁶ That these substances cannot be detected in 10 to 50 cc. of serum available for clinical determination is therefore not surprising. For practical

purposes the serum may be considered as lacking cerebrosides in determinable quantities³⁷⁻³⁹ The cerebrosides are built and metabolized within the cells where they are encountered In contrast to serum, normal red cells show cerebrosides in measurable amounts Dried red cells contain 0.2 per cent, consisting entirely of galactosidocerebrosides³⁷

In Gaucher's disease the cerebrosides are accumulated in reticulum cells and histiocytes of the spleen, liver, lymph nodes and bone marrow (4 to 20 per cent) In contrast to the organs, the serum of patients with Gaucher's disease, like that of normal subjects, does not contain measurable quantities of cerebrosides,³⁷ and the concentration of cerebrosides in the red cells is not elevated above normal For these reasons the analysis of serum and red cells for cerebrosides cannot be used for diagnostic purposes in Gaucher's disease

Aghion⁴⁰ and Halliday and his co-workers⁴¹ found that the cerebrosides that are accumulated in the

cell, which may originate from an increased synthesis and retention of cholesterol in the cell itself — this process is effected without increased supply of cholesterol and cholesterol esters from the bloodstream, and extracellular precipitation or crystallization of cholesterol, which may be observed within the inflamed wall of the gall bladder or the degenerating wall of an arteriosclerotic vessel, which may occur without an increase of cholesterol in the serum and which is due to degenerative changes of the surrounding medium altering the physicochemical state of substances that are not in ionized solution in bile or serum, like cholesterol and part of the calcium

The first and the second mechanism may result in xanthoma-cell (foam-cell) formation characteristic of the various types of xanthomatoses

Thannhauser and Magendanz⁴² and Thannhauser⁴⁴ classified the xanthomatous disorders according to the laboratory findings in the serum

visceral organs of patients with Gaucher's disease are not, as was formerly believed, galactosidocerebrosides but consist entirely of glucosidocerebrosides In 3 cases of Gaucher's disease examined in our laboratory, 2 showed only glucosidocerebrosides, 8.3 and 11.3 per cent respectively, and 1 contained 7.2 per cent glucosidocerebrosides and 8.6 per cent galactosidocerebrosides³⁷ In the infantile form of Gaucher's disease, in contrast to the adult form, only the galactoside variety of cerebrosides is found in increased concentration in the organs⁴² Up to the present only this one case of infantile Gaucher's disease has been examined for the variety of cerebrosides*

CHOLESTEROL AND ITS ESTERS

One should consider three different possibilities for the etiology of cholesterosis in cells and tissues cholesterol infiltration into the cell, a process that results from an accumulation of cholesterol and cholesterol esters in the serum (hypercholesteremia), cholesterol accumulation and retention within the

of these patients The figures resulting from the quantitative analysis of lipids in serum are characteristic of three different groups of xanthomatous disease and hence of great value for their differential diagnosis

A high serum cholesterol, a normal cholesterol/cholesterol ester ratio, a moderately increased lecithin in the serum but a normal serum value for neutral fat (serum is transparent) are found in essential xanthomatosis of the hypercholesteremic type (hypercholesteremic familial xanthomatosis) Characteristic of this group are tuberous or planar xanthomas of the skin (similar to yellow carotene in color), xanthomas of tendons, atheroma formation in the intima of blood vessels and of the endocardial lining of the heart and xanthomas of the lining of bile ducts

Normal cholesterol, lecithin and neutral-fat values of serum are observed in essential xanthomatosis of the normocholesteremic type (normocholesteremic xanthomatosis — synonymous with eosinophilic granuloma, Schüller-Christian syndrome and eosinophilic xanthomatous granuloma) The organs involved in this syndrome — singly, in various

*In the meantime examination of the organs of the patient's brother showed glucosidocerebrosides and galactosidocerebrosides

combinations or generalized—are the skin (disseminated type of skin xanthoma), osseous system, dura, brain, lungs, pleura, lymph nodes and spleen.

Enormously increased values of neutral fat (milky or creamy serum) but only moderately increased values of cholesterol and lecithin are characteristic of idiopathic hyperlipemia with secondary eruptive xanthomas and of related syndromes in which severe hyperlipemia is the primary cause. Parallel with the degree of hyperlipemia, inflammatory skin xanthomas appear and disappear. In visceral organs only a few scattered foam cells may be found.

Hypercholesteremia and Xanthoma Formation

The concentration of cholesterol in the serum seems to depend on many factors. Some of the possible causes of hypercholesteremia and xanthoma formation are discussed below.

Diminished destruction. Thus far, no enzyme capable of splitting the terpen-like ring of cholesterol

ments³¹⁻³³. In these experiments cholesterol was determined as cholesterol-digtonid. From the fact that the expected amount of cholesterol did not precipitate with digtonin it cannot be concluded that the cholesterol skeleton was destroyed in the intermediary metabolism. The sterol nucleus may well have been intact, whereas oxidative or reductive changes may have resulted in a sterol unprecipitable with digtonin or not giving the Liebermann-Burchard test. Since it has been shown that bacteria present in the intestinal tract transform cholesterol to a sterol not precipitable by digtonin,^{37, 38} it may be concluded that the deficit of cholesterol in balance experiments in animals, as well as in man, is due to a bacterial action on cholesterol in the intestines rather than to a disintegration of the sterol ring in the intermediary metabolism. On the basis of present knowledge an accumulation of cholesterol in the blood serum or in the tissues cannot be explained by a diminished

TABLE 2 (Continued)

has been isolated from mammalian tissues. The chemical changes that occur in the intermediary metabolism of the cholesterol molecule take place in the side chain of that molecule, such as esterification of the alcoholic hydroxyl group, hydrogenation and oxidation of the sterol ring as well as of the side chain. It is not definitely known whether the sterol sex hormones are metabolites of cholesterol or the result of sterol synthesis, notwithstanding the fact that pregnanediol glycuronate containing deuterium was isolated from the urine of a pregnant woman after feeding of deuterium containing cholesterol.⁴⁰ Cholesterol derivatives in minimal quantities have been isolated from animal organs. It was suggested that cholestenone was present in deposits of cholesterol in the arterial wall.^{44, 47} Hydrocholesterol has been isolated from the liver and from the serum of pregnant mares.⁴⁸ Dicholesteryl ether is present in the spinal cord of the ox.⁴⁹ Cholestenone is produced by the action of proactinomycetes on cholesterol.⁵⁰

A destruction of the cholesterol skeleton was concluded from negative cholesterol balance experi-

ments.⁵¹⁻⁵³ In these experiments cholesterol was determined as cholesterol-digtonid.

Increased formation. As stated above, enzymes capable of splitting the sterol skeleton are not known to be active in the intermediary and cellular metabolism of animals. Consequently, an accumulation of cholesterol due to an intracellular enzymatic disturbance is not likely to be the result of a decreased cholesterol catabolism but rather of an increased anabolism—that is, increased synthesis of cholesterol. Earlier investigations of cholesterol metabolism have shown that the sterol-ring system is constantly synthesized in the mammalian organism.^{33, 38-41} Schoenheimer,⁴² by the administration of materials containing deuterium, demonstrated that the small molecules of two and three carbon atoms, which may be derived from all three food constituents (protein, carbohydrates and fats) are the basis of cellular sterol synthesis. Macleod and Smedley-MacLean⁴³ had already shown in 1938, by the use of acetic acid labeled with deuterium, that yeast is able to synthesize more than 50 per cent of its cholesterol from acetic acid. Bloch,^{44, 45} in 1942,

employing labeled acetic acid in experiments with rat-liver slices, also demonstrated that considerable quantities of cholesterol are synthesized from acetic acid in the liver. The question that arises is, Which organs and cells are capable of cholesterol synthesis? Even if there is no definite answer, it is probable that every growing cell during maturation is capable of synthesizing cholesterol. This function in later life seems to be maintained in rapidly proliferating histiocytes and reticulum cells in certain disorders in which the functional capacities of embryonal cells — especially embryonal fat cells — to form all kinds of lipids are apparently preserved^{66, 67}. In the fully developed organism the liver apparently plays a special part not only in the excretion but also in the synthesis of sterols. The experiments of Thannhauser, Enderlen and Jenke⁶⁸ on dogs with bile fistulas demonstrated that the synthesis of the sterol skeleton of bile acids occurs as a biologic synthesis in the liver. In further experiments it was shown that after liver extirpation in dogs the serum cholesterol is not considerably decreased after twenty-four hours⁶⁹. The lowest cholesterol values, however, are observed in the serum of patients with acute yellow atrophy of the liver⁷⁰. This observation supports the theory that the liver plays an important role in the formation of cholesterol in the mature organism. Different clinical manifestations may occur whether the increase of cholesterol formation takes place in or outside the liver. It may be suggested that the clinical syndrome designated by Thannhauser and Magendantz⁴³ as "primary essential xanthomatosis of the hypercholesteremic type" — with hypercholesteremia, hyperlecithemia but normal neutral fat content of the serum as the leading clinical signs — is the result of increased cholesterol and lecithin formation in the organism, possibly in the liver. The exact site of the increased formation of cholesterol, however, has not yet been ascertained.

This syndrome (hypercholesteremic familial xanthomatosis) is characterized by xanthoma formation in the skin (plain and tuberos xanthomas), xanthomas of the tendons, in which the nodules consist of cholesterol-containing foam cells and fibrous tissue, and xanthoma of the intima of the blood vessels and of the endocardial lining of the heart. The incidence of this syndrome in families as a recessive hereditary stigma is of great interest. The complete syndrome may be present in members of the same family, whereas in others only hypercholesteremia may be found — the incomplete form or *forme fruste*^{43, 71, 72}.

Increased formation in the liver and impaired excretion. An imbalance of cholesterol formation and excretion is suggested as the cause of xanthomatous biliary cirrhosis, a syndrome that is characterized by the following clinical symptoms: skin xanthomas of the plain and tuberos variety, enlarged liver and spleen, obstructive type of jaundice of years' dura-

tion, extremely high values for total cholesterol (increased four to six times normal) and extremely high values for lecithin (increased four to eight times normal), transparent serum and diminished values for neutral fat in the serum despite the outstanding increase of cholesterol and lecithin^{43, 73-76}.

On the basis of newer anatomic observations Thannhauser⁷³ has reconsidered his previous opinion concerning xanthomatous biliary cirrhosis and now suggests that the imbalance of cholesterol and lecithin formation and excretion is at the outset a functional disturbance of the liver⁷⁷. In later phases anatomic changes in the bile capillaries (cholangioles) lead to a special type of biliary cirrhosis¹. MacMahon and Thannhauser⁷⁸ in a study of the livers of 5 patients showing the typical clinical signs of xanthomatous biliary cirrhosis, as described above, found in the early stages a nonspecific chronic inflammatory reaction centered about the smallest bile ducts and junction ducts of the portal areas. There was blocking of the ducts and subsequent intralobular bile stasis. The larger bile ducts were patent and free.

Xanthomatous biliary cirrhosis is an independent clinical syndrome, occurring together with plain and tuberos xanthomas of the skin, xanthoma formation in the intima of the blood vessels and the endocardial lining of the heart and xanthomas in the lining of the bile ducts. In contrast to previous opinion, the xanthoma formation in the lining of the bile ducts, with resulting obstruction, is not considered the cause of xanthomatous biliary cirrhosis, since it was not found in 3 cases at autopsy⁷⁸. For this reason it is believed that xanthoma formation in the lining of the bile duct may occur in rare cases, similar to atheroma formation in arteries, as one of the possible features of but not as the cause of the disease.

Impaired excretion due to hepatitis. In almost all cases of epidemic hepatitis or of toxic hepatitis in its acute or chronic stages, the total cholesterol in the serum is increased. The value of cholesterol present as esters in the serum (normally 70 to 75 per cent of the total cholesterol) decreases in proportion to the severity of the acute liver-cell damage. During convalescence the total cholesterol, as well as the cholesterol present as esters, gradually returns to normal. In chronic hepatitis the values for the total cholesterol are slightly increased, whereas the cholesterol present as esters remains low. In acute yellow atrophy of the liver the total cholesterol is below normal, signifying that insufficient functioning liver parenchyma remains for cholesterol synthesis. In these cases the lowest cholesterol values are observed⁷⁰.

Mechanical obstruction of common bile duct. This condition, due to stone, inflammation or tumor, results in a retention of all bile constituents and consequently of cholesterol. The serum of patients

*Pericholangiolitic miliary cirrhosis

suffering from mechanical obstruction of bile ducts does not usually show extremely high cholesterol figures (one or two times normal). The ratio of cholesterol to cholesterol present as esters is altered only if acute or chronic damage of the liver cells accompanies the mechanical obstruction.⁷⁰⁻⁷²

Hypercholesteremia of greater degree (three or four times normal) may develop after injury of the common bile duct during an operation resulting in its complete obliteration. Notwithstanding complete obstruction of long duration, skin xanthomas usually do not develop. The occurrence of secondary xanthomas has been reported only rarely, and these have disappeared because the patency of the common duct has been restored.⁷⁶

Hyperlipemia The cholesterol content of the blood serum may be increased without functional or mechanical impairment of cholesterol excretion in cases in which hyperlipemia (creamy serum) occurs. Hyperlipemia may be due to an increased transportation or diminished deposition of neutral fat, as pointed out above. Whenever neutral fat increases in the serum, cholesterol accompanies the neutral fat and results in an increase of free cholesterol and cholesterol esters. In such cases foam cells are caused by an increased uptake of fat and cholesterol from the serum (cholesterol infiltration) and are observed especially in the skin and to a minor degree scattered in the spleen, liver and lungs.

The clinical syndromes in which xanthoma formation secondary to hyperlipemia may be encountered are as follows: idiopathic hyperlipemia with secondary xanthomatosis (slight diabetes may or may not be present, the hyperlipemia and xanthomas disappear after neutral fat is restricted in the diet, insulin is not effective in the treatment of hyperlipemia in these cases)⁶⁸, hyperlipemia with secondary xanthomatosis due to untreated severe diabetes mellitus⁶¹ (insulin treatment alone corrects the diabetic condition as well as the hyperlipemia, and the xanthomatous eruption consequently disappears), idiopathic familial hyperlipemia²⁻³ (these cases are favorably influenced by a diet low in fat, the hyperlipemia never completely disappears but is considerably reduced), idiopathic hyperlipemia, hepatosplenomegaly and secondary xanthomatosis with hepatosplenomegaly of the Bürger-Grütz type⁶ (this is probably a variation of the syndrome, idiopathic hyperlipemia), hyperlipemia in chronic pancreatitis (this may cause secondary xanthoma formation in rare cases¹⁰⁻¹²), and hyperlipemia in severe cases of glycogen-storage (von Gierke's) disease (the occurrence of secondary xanthoma in this disorder is rare¹³⁻¹⁵).

Hypothyroidism In cases of hypothyroidism the cholesterol content of the serum is elevated. The reason for this increase is not known. Thyroid medication reduces the cholesterol level of the serum in these patients. In rare cases of hypothyroidism with high serum cholesterol levels, foam

cells with xanthoma formation may be found in the skin.⁶⁶ Neutral fat and total phospholipids are not increased or show only a slight rise.⁶⁸ In hyperthyroidism the total cholesterol level in the serum is a low normal or sometimes below normal. The cholesterol-cholesterol ester ratio in hypothyroidism and hyperthyroidism is normal.

(To be concluded)

CASE 33401

PRESENTATION OF CASE

A thirty-year-old housewife entered the hospital because of shortness of breath and a mass on the chest wall.

The patient had experienced episodes of dyspnea with emotional stress for three years. A year before admission she had been seen in the Out Patient Department, and the dyspnea was thought to be due to an anxiety state. No mass was noted at that time, although the patient stated that she had first noted it following a fall eighteen months before admission. The mass continued to grow and became tender. She noted weakness for several months and lost 5 to 10 pounds. A month before admission she was seen at another hospital, where a mass was observed over the left seventh rib anteriorly and bloody fluid was removed from the left pleural space. For three days prior to admission she had chills and fever.

Physical examination revealed an acutely ill woman perspiring freely. Over the left seventh rib anteriorly near the costal margin was an extremely tender, hard, fixed mass 6 by 4 by 3 cm. The left side of the chest was flat to percussion, with absent breath sounds posteriorly on the left.

The temperature was 99.6°F, the pulse 100, and the respirations 20. The blood pressure was 110 systolic, 70 diastolic.

The urine had a specific gravity of 1.014 and contained no albumin, and only rare white cells and granular casts were observed in the sediment. Examination of the blood revealed a red-cell count of 3,200,000, with 11 gm. of hemoglobin, and a white-cell count of 11,500. The total protein was 6.3 gm. per 100 cc.

On the first hospital day 100 cc. of serosanguineous fluid was removed from the left pleural cavity. The specific gravity was 1.022. On smear no tumor cells were seen. An x-ray film of the chest following the tap showed fluid in the left pleural cavity forming a fluid level opposite the tenth vertebral body posteriorly. A moderate pneumothorax was present on the left. The heart and mediastinum were dis-

placed to the right. The left lower lobe was collapsed. There was mottling of the bone structure of the anterior portion of the seventh rib with some new-bone formation.

On the second hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. CLIFFORD C. FRANSEEN. The significant findings from which we may get some leads are: the age of the patient (thirty years), the duration of the symptoms, — there is some question whether it was three years or eighteen months before admission, when she had the fall, that she first noticed the mass, — the slight fever, the extremely tender character of the mass on the chest wall, the probable secondary anemia, the elevation of the white-cell count, the exudative character of the pleural fluid that was removed and the fact that the lesion in the rib showed bone destruction and some new-bone formation. In every case of this kind, with a lesion in the bone, we have repeatedly emphasized the importance of reviewing the case from several aspects. In the first place, is it a neoplasm, and if it is neoplastic, is it primary or metastatic? If primary, is it benign or malignant? Then, is it an inflammatory or granulomatous lesion, or does it have a metabolic basis? One by one, we try to exclude these possibilities and to arrive at some conclusion regarding the character of the lesion.

When this patient was seen a year previously in the Out Patient Department no mention was made of an x-ray examination. Of course, that was the time to take an x-ray film. The patient had been aware of the mass six months previously. This lesion might have been discovered at that time.

If we consider neoplasm, was it primary? It could have been primary in the rib or perhaps, from this description, in the pleura, and there is a remote possibility that it was in the lung. Primary tumors of the pleura are quite rare, of course. Secondary invasion of the rib or destruction of the rib, from a pleural tumor, is not common, and altogether the picture does not fit too well with primary tumor of the pleura. Among the tumors of the pleura, the so-called "endotheliomas" are the most frequent. They may produce pleural effusion, but usually not of such a high specific gravity as the tumor in this case showed.

The primary tumors of the rib must, of course, be considered more seriously. It might be well to look at the x-ray films, because they are important in a case of this nature.

DR. STANLEY M. WYMAN. The films, taken six days apart, show fluid in the left pleural cavity with a small amount of air above. The rib detail is unsatisfactory in the first two films but suggests on the later films some mottling and destruction in the body of the rib. The distal 5 or 7 cm. of the rib shows multiple destructive areas in the body of the

medulla, with some periosteal reaction. There is slight bone reaction with increased density in the rib.

DR FRANSEEN: Is there any expansion of the cortex?

DR WYMAN: It does not appear to be expanded.

DR FRANSEEN: So far as the x-ray studies are concerned the important findings include a bone-destructive lesion that is producing new bone. Among the primary tumors of the rib one must consider almost the entire field. Osteogenic sarcoma of the rib, of course, is quite rare. In this group, the chondrosarcomas are more frequent. They can, of course, be osteoplastic and produce new bone, but my impression is that the new-bone formation would be of a different type than that seen in the case under discussion, which is somewhat irregularly distributed. Multiple myeloma is a fairly common tumor of the rib, but it is a purely destructive lesion, almost without exception, and it does not form new bone. Pathologic fractures in these latter lesions are very common, but there is no fracture here or thinning to any extent. Hodgkin's disease, in particular, may affect the rib but usually in the late stages of the disease, and we have no real evidence for including that lesion.

Ewing tumor is not an uncommon lesion at this site and may produce new-bone formation with effusion into the chest cavity. I do not see how one can entirely exclude that possibility.

Metastatic lesions of the rib are perhaps the most frequent statistically. This patient was a relatively young woman, and we have no evidence for considering a metastatic lesion on the basis of the data provided us. Metastatic lesions of this type usually do not produce new bone in a rib.

We must consider inflammatory lesions seriously because of the extremely tender character of the mass, the slight fever and some leukocytosis. Many of the slowly developing, inflammatory lesions of bone can produce both bone destruction and new-bone formation. Some of the granulomatous types, like syphilis, might be considered, and although no serologic findings are reported, there is no reason for considering syphilis seriously. I mention it because almost all bone tumors may on occasion be simulated by syphilis or by tuberculosis, which can perhaps also be excluded.

We then come to a consideration of chronic osteomyelitis. This must have been a relatively chronic process, with an acute episode toward the end, with chills and fever and with exudate in the pleural cavity. We know that chronic osteomyelitis may persist in bones like this for a long time with relatively little reaction. The patient had a fall with apparent injury at that site, although not necessarily, because after a fall people feel themselves all over and discover masses that were present prior to the injury. Women, particularly, are apt to discover

masses in the breast under such circumstances and to say that the mass was due to a fall.

There are diseases such as eosinophilic granulomas of the rib, which are quite rare, and I am not familiar with all the variants that can occur in them because of the paucity of cases that have been recorded. Whether it can simulate this lesion, I am not prepared to say. A biopsy would be necessary to establish these diagnoses.

So far as metabolic lesions go, we have nothing in the report to suggest that this lesion had a metabolic basis. The only blood chemical finding reported is the total protein, which was not remarkable. The determination is important, of course, in the consideration of multiple myeloma, in which it is almost always elevated.

In putting all these facts together we find that the duration was relatively long for a malignant process in the rib. If it were a malignant tumor, it would have to be relatively slowly growing. I cannot escape the impression that this was an inflammatory lesion—probably some form of chronic osteomyelitis with late pleural effusion. The fluid may have been present for a longer time, but it was the pleural reaction that brought the patient to the hospital. I had to choose among these various diagnoses, should put osteomyelitis first, but with the reservation that many of the other lesions that I have mentioned cannot be excluded except by biopsy.

CLINICAL DIAGNOSIS

Ewing tumor?

DR FRANSEEN'S DIAGNOSIS

Chronic osteomyelitis of rib

ANATOMICAL DIAGNOSIS

Ewing tumor of rib and phalanx of toe.

PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN: This lesion was first aspirated with a large needle, and all that could be removed was some connective tissue in which there were a few deeply stained cells that we could not make anything of. They were apparently traumatized in the aspiration biopsy, and we believed that the biopsy was inadequate to make a diagnosis. The patient was then admitted to the hospital, and an open biopsy performed, which showed a Ewing tumor of a rather typical form, but without, at least in our biopsy, any evidence of reaction.

A week after the biopsy the right fourth toe became painful and swollen. The patient stated that this had occurred intermittently for about a year. An x-ray film was taken, and Dr Wyman will show the films.

DR STANLEY M. WYMAN: The proximal phalanx of the fourth toe shows multiple rather cyst-like areas that are, however, very ill-defined but somewhat indicative of destruction. There is a slight suggestion of a little periosteal reaction.

Dr. CASTLEMAN Will you discuss the lesion in the toe, Dr. Franseen?

Dr. FRANSEEN It is unfortunate that the patient did not have this four days earlier because with a multiplicity of lesions, I should have been more willing to accept a diagnosis of Ewing tumor. We know that Ewing tumor, more frequently than any other bone tumor, produces a response suggestive of inflammation in these various sites, and the appearance of this additional lesion would be entirely consistent with it.

Dr. CASTLEMAN Have you ever seen metastases of Ewing tumor in the phalanges?

Dr. FRANSEEN I do not remember that I have seen one.

Dr. WYMAN I think that they are extremely rare, but I believe that we have seen one.

From the x-ray films I should not have thought that the lesion in the toes was Ewing tumor. The roentgenogram is consistent with it, but the toe is an unusual location.

Dr. FRANSEEN I should certainly not be able to make a diagnosis from this x-ray film of the toe.

Dr. CASTLEMAN The toe was amputated and also proved to contain a Ewing tumor. I believe that it is the first one we have seen in this location. Geschickter* mentions a few in the tarsus and metatarsus but none in the phalanx. The fact that no lesions are seen on the films of the other bones raises the remote possibility that the toe lesion was another primary tumor. The chances are, however, that this is the first of other metastases that will become evident later. The patient is receiving x-ray treatment over the rib.

*Geschickter, C. F., and Copeland, M. M. Tumors of bone. *J. Nerv. & Ment. Dis.* 10: 323-343, 1930.

CASE 33402

PRESENTATION OF CASE

A fifty-four-year-old married woman entered the hospital with the complaint of lower abdominal cramps of two days' duration.

The present illness began abruptly about forty-eight hours before admission. There were severe lower abdominal cramps with continuous aching and a sense of fullness. The patient was nauseated and vomited several times without relief. There was no change in bowel habit, and no urinary symptoms were noted. She felt feverish but had no chills. She was seen by a physician, who noted a mass in the lower abdomen. Pelvic examination revealed a firm, somewhat movable and tender tumor about the size of an orange occupying the apex of the vagina in the region of the cervix; no other mass could be felt. The pain was relieved temporarily by morphine but recurred. Hospitalization was advised.

The patient's health had always been excellent. An appendectomy had been performed twenty-seven years before admission. The menstrual history was normal. She had had two children without complication. Two years before admission the menstrual periods had ceased. There was moderate annoyance from hot flashes and sweats, and she had severe mental depression. These symptoms were relieved by estrogens, and some form of hormone therapy had been administered up to the time of admission to the hospital. Approximately four months before admission conization of the cervix was carried out to relieve a complaint of vaginal discharge.

Physical examination disclosed a flushed and somewhat dehydrated woman in some distress. The abdomen was soft, and peristalsis was normal. There were tenderness and a sense of an asymmetrical mass in the suprapubic area. Pelvic examination was essentially as described above.

The temperature was 99.4°F., and the pulse and respirations were normal. Examination of the blood revealed a hemoglobin of 11.6 gm. and a white-cell count of 8700. A catheter specimen of urine showed no albumin or sugar, the sediment contained rare red cells and 12 white cells per high-power field. Cytologic examination of the vaginal secretion was negative.

There was no change in the patient's condition overnight. On the day following admission an operation was performed.

DIFFERENTIAL DIAGNOSIS

Dr. FRANCIS M. INGERSOLL The tender, movable mass occupying the apex of the vagina must have accounted for the symptoms of the low abdominal cramps and a sense of fullness. The description of the pelvic examination failed to note if the cervix was present in addition to the mass or whether this mass was actually the cervix. No mention was made of the size, shape or position of the uterus, although a symmetrical mass in the suprapubic area was described. The uterus and cervix must have been present, since the only previous operation was an appendectomy. To arrive at a diagnosis in this case it is necessary only to decide what the mass in the pelvis was.

This mass seemed to be so close to the vagina that an ovarian tumor can probably be ruled out. If the patient had had a previous total hysterectomy the mass could have been an ovarian tumor adherent to the vaginal apex, but since the uterus was apparently still present, ovarian tumors could not have occupied this position.

A vaginal cyst or tumor displacing the cervix and uterus is a possibility. Gartner's duct—a tube that is the homologue of the vas deferens, and a relic of the embryonic wolffian duct—occasionally causes cystic masses in the vagina, but they are usually on the lateral vaginal wall, rarely cause pain and

should have been discovered at the conization operation four months previously. Inflammatory masses are ruled out by the lack of fever and the normal white-cell count.

The field is narrowed down, then, to some lesion of the cervix itself. Cervical fibroids sometimes distort the entire organ and may become orange sized, but the patient was fifty-four years of age and fibroids do not develop in that age group, since it must be assumed that they were not present four months previously.

An enormous Nabothian cyst might feel like this tumor at the apex of the vagina. These cysts are unlikely to reach such a size. Moreover, two facts in the history can be correlated to account for this mass in the vagina: the patient had had a conization of the cervix, and she had been taking estrogens for hot flashes and mental depression. A common occurrence after estrogen therapy is uterine bleeding. No mention of any postmenopausal bleeding is found in the record. A frequent complication following conization of the cervix is stenosis of the cervical canal, with trapping of blood in the uterus. A distention of the cervical and endometrial canals occurs, causing pain and a sense of fullness in the pelvis. This diagnosis of cervical occlusion with distention of the cervical and endometrial canals with blood best explains the clinical picture in this case.

CLINICAL DIAGNOSIS

Hematometrium due to cervical stenosis

DR INGERSOLL'S DIAGNOSIS

Hematometrium due to cervical stenosis

ANATOMICAL DIAGNOSES

Hematometrium due to cervical stenosis

Adenomyosis of uterus

PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN: Will you tell us what was found at operation, Dr Ulfelder?

DR HOWARD ULFELDER: Under anesthesia one could easily feel a movable, smooth, rounded pelvic tumor about the size of a grapefruit. It was palpable

in the suprapubic region and presented at the apex of the vagina as a fluctuant, rounded surface with no sign of the cervix. One small dimple suggested the external os. A needle inserted here aspirated dark blood. The opening was enlarged, and free drainage allowed for a large hematometrium.

Eight days later an abdominal hysterectomy was performed. The uterus had shrunk to normal contour and was easily removed, together with the cervix.

DR CASTLEMAN: On opening the specimen it was apparent that the cervix was markedly constricted at the external os and had been greatly expanded and thinned out by the accumulation of secretions and blood. The fundus had been only slightly involved and had risen on top of the expanding cervix. Microscopically, the area of stenosis showed only chronic inflammation. The myometrium was extensively involved with adenomyosis.

DR ULFELDER: Stenosis of the cervix following by hematometrium or pyometrium is a complication not infrequently seen after application of radium or cauterization. It may occur without antecedent trauma as a result of menopause atrophy alone. This is particularly true in patients in whom estrogen bleeding is induced after years of inactivity. Dr Ingersoll has emphasized the point that a combination of trauma to the cervical canal and uterine bleeding due to estrogens is the most frequent history in these cases. The usual site of stricture is at the internal os, since the canal is narrowest at this point, and in such cases a dilated and thinned uterine body with an undistorted cervix is still found to be present in the usual position. Occlusion at the external os, as in the case under discussion, is rare.

Although adequate drainage is easily established, two points must be kept in mind during the treatment of this condition: cancer as the cause of obstruction must be excluded, and there is a tendency for the inflammatory stenosis to recur if the uterus is not removed. If hysterectomy is not planned, a rubber T-tube catheter should be left in the fundus with the long arm out through the cervical orifice for at least three months, until a permanent channel can be established.

RED CROSS NATIONAL BLOOD PROGRAM

THE plans of the American Red Cross to administer and finance a program designed to provide, without charge, blood and its derivatives for all the people of the United States* is a fitting climax to the magnificent job done by this organization during the war. The extent of the program is indicated by the estimates that, eventually, about four million pints of blood will be needed annually and that nearly \$20,000,000 will be required each year to cover all costs. The great value of blood and its derivatives in the saving of human lives has been proved, particularly during the war, and there can be no doubt that a national enterprise of this sort is badly needed. Nor is there any question that the American Red Cross, which supplied more than

thirteen million pints of blood to the armed forces, is best qualified to undertake this gigantic effort as a peace-time service.

Four distinct phases are involved in the program: collection of the blood, its processing, packaging and storage, its distribution, and continuous research and investigation of the quality of the products and their proper usage. In addition to whole blood, the following derivatives will be provided: plasma serum albumin, immune serum globulin, anti-hemophilic globulin, blood-grouping serums, fibrin films and red-cell suspensions, paste and powder. Other products will undoubtedly be made available as soon as their usefulness in medicine and surgery has been proved. Under the guidance of the national organization, the general plan of operation will be handled by the Red Cross chapters, which will work in co-operation with the medical societies, public-health agencies, hospitals and other institutions in their communities.

It is expected that state or community programs already established will be given a further impetus through integration with the national endeavor to provide a greater variety of blood derivatives. In Massachusetts the burden of establishing such a program has been largely borne by the Department of Public Health and hospital and medical groups, the role of the Red Cross having been that of donor procurement and certain nontechnical local assistance. With the undertaking of a blood program as a major activity of the American Red Cross it may be possible to extend the program in Massachusetts, which, with the limited funds at present available, has never been able to catch up with the ever-growing requirements for blood and blood products in the Commonwealth.

A program such as this demands constant support of all concerned with it — as physicians or patients or in other capacities. The only way of ensuring the success that the endeavor must achieve if the needs for blood are to be met is for all concerned to give active aid and encouragement to every effort designed to make more blood available.

To put this program in operation in all sections of the United States will be difficult and will require time. But the benefits that will accrue are incalculable: there is no means of measuring the value

*McGrath G. F. National blood program inaugurated. *Red Cross Courier* 27:3 (July) 1947.

of the lives that will be saved and the suffering that will be alleviated by the immediate provision of blood and its derivatives, without cost, to the ill and injured. It is a typical undertaking of the American Red Cross in its goal to be of service to humanity, and it deserves enthusiastic and wholehearted support by all.

EPIDEMIOLOGY OF NEONATAL SKIN INFECTION

A RECENT paper by Allison and Hobbs* presents an interesting study on the epidemiology of pemphigus neonatorum. This investigation, conducted between November, 1943, and November, 1945, in the nursery of a maternity unit in Cardiff, Wales, was occasioned by a recent considerable increase in the infection, particularly in the nurseries of this and similar obstetric hospitals.

During the period of the investigation 2719 infants were born in or admitted to the hospital, of these, 111 (4.1 per cent) developed pemphigus. In addition, 25 cases of staphylococcal conjunctivitis occurred, either alone or in association with the pemphigus.

It is notoriously difficult to trace staphylococcal migrations on account of the varieties of strains and the ubiquity of the organisms. The study was nevertheless attempted, painstakingly and meticulously, with culturing of the lesions, the noses, the eyes and, in some cases, the umbilici of the infants, of the noses and the throats of the mothers, doctors, attendants and nurserymaids, of the air and the dust of the nursery, and of the blankets and the gowns. The infecting organism, a coagulase-positive staphylococcus, frequently in pure culture, was obtained from every lesion investigated, and the strains were checked serologically. A low correlation was found between mothers and infants: rarely a mother developed a sore throat, apparently from her infected infant, and the converse was never noted. But the organism was found to be widespread in the infants' environment, being recovered from the noses and throats of some of the healthy infants, from the blankets, gowns, dust and air and particularly, from a high proportion of the noses of

*Allison, V. D., and Hobbs, B. C. Inquiry into epidemiology of pemphigus neonatorum. *Brit. M. J.* 2 1-7, 1947.

the nursing staff. It must be admitted that nursery conditions during most of the period of the study were not good, since the nursery was badly overcrowded, as well as poorly lighted and ventilated because of air-raid precautions.

The implications of this study are obvious, and they give added emphasis to knowledge already possessed regarding discharges from the human nasopharynx. These constitute a significant, if not the most important, source of staphylococcal, streptococcal and other infections of this type, and the carrier, regardless of the precautions taken, has no place in an infant nursery or surgical operating room or ward or, indeed, in any manner of close contact with other persons. No great imagination is necessary to conjure up a number of links in the chain of infection—the iniquitous pocket handkerchief, with hands unwashed after its use, the popular swimming pool or bathing pond and the family toothbrush holder.

In the nursery nothing can take the place of adequately developed consciences and a technique that has become automatic through intensive training. This study introduces further evidence in favor of the isolated mother-infant unit in maternity departments.

MASSACHUSETTS MEDICAL SOCIETY BUREAU OF CLINICAL INFORMATION

All secretaries of various medical groups, such as special societies and alumni associations, are requested to notify the Bureau of Clinical Information regarding scheduled meetings, annual dinners and so forth. If such data are on file, it is hoped that duplication of dates can be avoided.

DEATHS

POTTER — Lester F. Potter, M.D., of New Bedford, died on August 17. He was in his seventy-fifth year. Dr. Potter received his degree from Bowdoin Medical School in 1897. He was a member of the New England Otological and Laryngological Society.

SHATSWELL — James A. Shatswell, M.D., of Beverly, died on August 26. He was in his eighty-fourth year. Dr. Shatswell received his degree from College of Physicians and Surgeons of Baltimore in 1890. His widow and a brother survive.

SPIEGL — Erwin D. Spiegl, M.D., of Lynn, died on April 6. He was in his forty-sixth year. Dr. Spiegl received his degree from Deutsche Universität Medizinische Fakultät, Prague, Czechoslovakia, in 1923. He was a member of the staff of the Lynn Hospital.

BOOK REVIEWS

The Journals and Letters of the Little Locksmith By Katharine B. Hathaway. 8, cloth 395 pp., with 17 illustrations by the author. New York: Coward-McCann, Incorporated 1946. \$3.75

Anyone who is interested in psychiatry will find this book revealing, and if the reader is concerned with the psychology of literary artists, he may find it doubly interesting. It presents the intimate story of a remarkable life spent struggling first with a severe deformity of the spine and then with the host of secondary problems that resulted from being "The Little Locksmith," which was the way in which the author chose to think of her disability. The psychological benefits from the illness compensated only partly for the original injury to her personality, and these compensations in turn led to complicated emotional situations which she describes in this book with unusual skill and some insight. She records her sensitive reactions and displays dynamic patterns in her behavior so carefully that the perceptive reader will be well repaid for the time he spends on the book.

One must read *The Little Locksmith*, an earlier book by the same author to appreciate the full power and courage of this extraordinary woman, who in some ways resembles Katherine Mansfield, although Katherine Hathaway had more to endure in the way of physical hardship. The setting of her story is in Salem, Massachusetts, but it also takes in Cambridge and Boston of course as well as Maine and travel in Europe.

Miss Hathaway's whole life was spent more or less in the care of medical specialists from spine to soul straighteners. She lived first in a Bradford frame and then in a hody brace for years. She had to take special exercises all her life, and could rest and work only in certain strained positions. In her younger days she had a psychoanalysis with Dr. Lettice DeForest, followed later by eclectic psychotherapy with Dr. Merrill Moore, who encouraged her in the writing of books. For the preservation and editing of her manuscripts, credit is due her brother Warren H. Butler of Salem, who, serving effectively in the role of literary executor, has made her books available to the public. Katherine Hathaway died in the prison of her deformed body on Christmas Eve, 1942 just before her first book was published, with heart failure due to increasing restriction of the heart and lungs secondary to the spinal curvature. *The Little Locksmith* immediately became a literary success and a Book-of-the-Month Club choice. She was showered with posthumous literary recognition. Her legend, as one of America's most unique woman writers, is now growing to such an extent, particularly in New England literary circles, that she is already a myth and may become a cult in a small way, especially among physically handicapped persons. Few people writing in recent years have recorded with such sincerity and vitality their innermost thoughts and few have left such an inspiring and beautiful documentation of their passage through life.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Clinical Allergy. A monograph on the management and treatment of allergic diseases. By Alexander Sterling, M.D. With the assistance of Bea Sterling Hollander, M.D. 8th, cloth, 198 pp., with 16 illustrations. New York: International Universities Press, 1947. \$5.00.

This manual discusses clinical allergic problems, especially from the viewpoint of diagnosis and therapy. The text is amplified with 51 case histories illustrative of various conditions. The price seems excessive for this small volume.

Gynecology with a Section on Female Urology. By Lawrence R. Wharton, Ph.D., M.D., assistant professor of gynecology, Johns Hopkins Medical School, assistant acting gynecologist, Johns Hopkins Hospital, and consultant in gynecology, Union Memorial Hospital, Hospital for the Women of Maryland and Church Home and Infirmary. Second edition. 8th, cloth 1027 pp., with 479 illustrations. Philadelphia: W. B. Saunders Company, 1947. \$10.00.

This second edition of a standard textbook, first published in 1943 has been revised to date. The sections on embryology and congenital malformations have been reorganized and rewritten. The technique of ureterotomy for ureteral stone has been amplified. A chapter on water cystoscopy, written by Dr. Charles L. Prince, has been added to the section on female urology, and a separate chapter has been devoted to the female urethra. New illustrations have been included in connection with new developments in operative technique.

ANNOUNCEMENT

Dr. Frank B. Colloten announces the removal of his office to 73 Bay State Road, Boston.

JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston

Lecture Hall, 9-10 a.m.

MEDICAL CONFERENCE PROGRAM

Wednesday, October 8 — The Pulmonary Segment as a Unit for Treatment. Dr. Richard H. Overholt.

Friday, October 10 — Pulmonary Embolism. Dr. Lewis Dexter.

Wednesday, October 15 — Pediatric Clinico-pathological Conference. Drs. James M. Baty and H. E. MacMahon.

Friday, October 17 — Gastritis. Dr. Seymour Gray.

Wednesday, October 22 — Uterine Retrodisplacements. Dr. George A. Bourgeois.

Friday, October 24 — Traumatic Shock. The physiologic effects of blood loss. Dr. F. A. Simeone.

Wednesday, October 29 — A Discussion of Clinical Otoliths with Demonstration of the Fenestration Operation. Dr. Philip E. Meltzer.

Friday, October 31 — Precautions in Handling Radioactive Materials in Medical Research. Dr. Shields Warren.

On Tuesday and Thursday mornings from 9:00 to 10:00 Dr. S. J. Thannhauser will give medical clinics on hospital cases. On Friday afternoons from 2:00 to 4:00 therapeutic conferences will be held with round table discussion. Dr. R. P. McCombs, Moderator. On the second and fourth Friday afternoons of each month Dr. Merrill Soeman will conduct x-ray conferences from 4:00 to 6:00. On Saturday mornings from 9:00 to 10:00, clinics will be given by Dr. William Dimetich. Medical rounds are conducted each weekday except Saturday by members of the Staff from 12:00 to 1:00.

All exercises are open to the medical profession.

NEW ENGLAND DERMATOLOGICAL SOCIETY

A regular meeting of the New England Dermatological Society will be held at the New Haven Hospital, New Haven, Connecticut, on Wednesday, October 8, at 2 00 p m. The meeting is open only to members and invited guests.

HARVARD MEDICAL SOCIETY

The first meeting of the Harvard Medical Society will be held in the amphitheater of Building D, Harvard Medical School, on Tuesday, October 14, at 8 p m. Members of the Biophysical Laboratory of Harvard Medical School will present a symposium entitled "Biological Problems Studied with Isotopes."

PROGRAM

- Rates of Biological Processes in the Intact Animal Dr DeWitt Stetten, Jr
Some Aspects of the Metabolism of Zinc as Studied with the Radioisotope Zn⁶⁵ Drs John G Gibson, 2nd, and Bert L Vallee
The Incorporation of Alanine into Protein Drs Ivan D Frantz, Jr, Robert B Loftfield and Warren W Miller
Tracer Studies of Gas Exchange in Man Drs A C Barger and E M Landis
Some Studies in Radioautographs Drs A K Solomon and J C Cobb

Subsequent meetings will be held on November 4 and December 19, 1947, and January 13, February 10, March 9, April 13 and May 11, 1948.

JOINT MEETING OF NEW ENGLAND SOCIETY OF ANESTHESIOLOGISTS AND AMERICAN SOCIETY OF ANESTHESIOLOGISTS, INCORPORATED

A joint meeting of the New England Society of Anesthesiologists and the American Society of Anesthesiologists, Incorporated, will be held in Boston on November 10.

PROGRAM

- 8 a m to 12 m Clinical demonstrations in operating rooms of the Massachusetts General Hospital, Massachusetts Memorial Hospitals, St Elizabeth's Hospital, New England Deaconess Hospital, New England Baptist Hospital and Boston City Hospital
12 30 p m to 1 30 p m Informal luncheon at the Hotel Sheraton
2 00 p m Scientific program at the Hotel Sheraton Dr Julia G Arrowood will speak on "Pain Mechanisms." Drs William H Sweet and William T Chapman will lead the discussion.
3 00 p m Dr L K Diamond will speak on the subject "Whole-Blood Transfusions and Untoward Reactions," which will be discussed by Dr C P Emerson.
7 00 p m Dinner at the Hotel Sheraton Dr B B Raginsky, of Montreal, Canada, will speak on the subject "Mental Suggestion as an Aid to Anesthesia."

INCREASED PAY FOR MEDICAL OFFICERS

According to a recent announcement by Major General Raymond W Bliss, Surgeon General of the Army, all officers of the Regular Army Medical and Dental Corps, as well as all medical and dental officers serving voluntarily on extended active duty, will be paid an additional \$100 a month. This addition to the incomes of such officers is regarded by the War Department "not as a pay increase but as an equalization measure designed to bring the incomes of Medical and Dental Corps officers more nearly in line with those of civilian doctors and dentists."

The additional compensation will be paid not only to officers who were on extended active duty as of September 1, 1947, the effective date of the act, but also to eligible officers of the Medical and Dental Corps who are commissioned in the Regular Army or Navy and who are volunteers for extended active duty within the limits of the act. The duration of these benefits is limited to the period of active service.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING THURSDAY, OCTOBER 9

FRIDAY, OCTOBER 10

- *9 00-10 00 a m Pulmonary Embolism Dr Lewis Dexter Joseph H Pratt Diagnostic Hospital
*10 00 a m-12 00 m Medical Staff Rounds Peter Bent Brigham Hospital
12 00 m-1 00 p m Clinicopathological Conference (Boston Floating Hospital) Joseph H Pratt Diagnostic Hospital

MONDAY, OCTOBER 13

- *12 15-1 15 p m Clinicopathological Conference Peter Bent Brigham Hospital

TUESDAY, OCTOBER 14

- *12 15-1 15 p m Clinicopathological Conference Peter Bent Brigham Hospital
8 00 p m Harvard Medical Society Amphitheater, Building D Harvard Medical School

WEDNESDAY, OCTOBER 15

- *9 00-10 00 a m Pediatric Clinicopathological Conference Dr James M Baty and H E MacMahon Joseph H Pratt Diagnostic Hospital
*12 00 m Grand Rounds and Clinicopathological Conference (Children's Hospital) Amphitheater, Peter Bent Brigham Hospital.

*Open to the medical profession

STREPTOMYCIN THERAPY IN 52 CASES OF BACTERIAL INFECTION*

LEWIS W. KANE, M.D.,† AND GEORGE E. FOLEY‡

BOSTON

STREPTOMYCIN, an antibiotic agent obtained from certain strains of *Actinomyces griseus*, was first described by Schatz, Bugie and Waksman¹ in 1944. Immediate interest was attracted to this agent because of its effectiveness in vitro against bacteria that had previously been resistant to the action of known antibiotic and chemotherapeutic agents. Animal studies have demonstrated that the toxicity of streptomycin is of a relatively low order,² and the results in the treatment of experimental infections have proved its effectiveness in vivo.³⁻⁵ Clinical trials in the past two years have confirmed its low toxicity and demonstrated its value in the treatment of infections known to be resistant to the action of penicillin and the sulfonamides, such as those produced by gram-negative bacilli. Among the human infections known to respond to streptomycin treatment are tularemia,⁶⁻⁸ meningitis due to *Haemophilus influenzae*,⁹ and urinary-tract infections due to gram-negative bacilli.^{4, 10} The results of treatment of 1000 miscellaneous cases have recently been reviewed by the Committee on Chemotherapeutics of the National Research Council.¹¹

It is the purpose of this paper to report in detail the results obtained in 52 cases treated with streptomycin. In this group are included urinary-tract infections, meningitis and epiglottitis due to *H. influenzae*, bronchiectasis, nonspecific urethritis and 1 case of septicemia caused by *Pseudomonas aeruginosa*.

MATERIAL AND METHODS

All patients treated with streptomycin were hospitalized at the Massachusetts General Hospital or the Massachusetts Eye and Ear Infirmary.† They

were selected on the basis of the infecting organism after careful bacteriologic study. Most patients had previously been treated with penicillin or one of the sulfonamides and had failed to make a satisfactory clinical response. In most cases streptomycin was administered intramuscularly. Topical and aerosol streptomycin were used in certain cases in which they were considered to be of possible value.

Determinations of streptomycin sensitivity and body-fluid levels of the drug were carried out when indicated, according to the method described by Price, Nielsen and Welch.¹

URINARY-TRACT INFECTIONS

Pyelonephritis and Cystitis

Thirty-eight cases of pyelonephritis and 2 cases of cystitis were treated with streptomycin (Table 1). These cases were selected on the basis of infections due to gram-negative bacilli. In 32 cases the infecting organism belonged to the colon-aerogenes group. Of the remainder, 2 were due to *Ps. aeruginosa* and 2 to *Proteus vulgaris*, and 4 were mixed infections due to *Escherichia coli* in combination with *Ps. aeruginosa* in 3 cases and *Pr. vulgaris* in 2. No cases were treated in which indwelling catheters were being used. Cases with nonobstructing renal calculi or partial ureteral strictures were not excluded in this study, since it seemed important to determine the effect of streptomycin in the presence of these complications. Except when contraindicated, sulfonamides and less frequently mandelic acid and penicillin were employed in all cases prior to the initiation of streptomycin therapy.

A 0.1 per cent streptomycin solution in physiologic saline was given intramuscularly on a four-hour schedule, but the 2-a.m. dose was usually omitted because it was observed that effective urinary levels were maintained during the 10-p.m. to 6-a.m. interval. The total dosage varied from a minimum of 0.5 to a maximum of 2.0 gm a day. At first all cases were treated with 1 gm daily for ten days, but as more experience was gained, it was found that smaller doses (0.5 gm)

‡Assistant bacteriologist, Massachusetts General Hospital.

[The streptomycin used in these studies was provided by the National Research Council from supplies assigned for clinical investigations recommended by the Committee on Therapeutics and Other Agents.

This study was made possible by the close co-operation of the visiting and house staffs of the medical, surgical and pediatric services of the Massachusetts General Hospital and Massachusetts Eye and Ear Infirmary. We are indebted to Mrs. W. C. H. for aid in the technical work and the preparation of the manuscript.

given for as little as three or four days were sufficient in cases in which the infecting organisms were extremely sensitive. In cases in which it was impossible to obtain the sensitivity of the infecting organism prior to the institution of therapy, 1 gm daily was used as an initial dose, and the response

three days and in 1 each within four and five days. The duration of therapy varied according to the rapidity with which the organisms disappeared from the urine. It soon became apparent that it was not necessary in most cases to continue treatment for more than three days after the urine first became

assayed by daily urine cultures. When this method was used, the dosage was raised if there was no response within three or four days. The reliability of this method is indicated by the fact that of the 30 cured patients followed by daily cultures while on streptomycin therapy, the urine in 17 (57 per cent) became sterile within one day, in 8 (26 per cent) within two days,* in 3 (10 per cent) within

sterile. In no case was therapy continued for more than eleven days.

Whenever possible, the fluid intake was restricted to 2000 to 3000 cc daily. On the basis of the work done by Abraham and Duthie,¹³ in which it was demonstrated that streptomycin is most effective in an alkaline medium, the urine was alkalinized in the majority of cases by means of sodium citrate. One teaspoonful of a 50 per cent solution was given orally three times daily. The reaction of each specimen

*In 4 of these cases the urine was not cultured until the second day, and hence may actually have been sterile on the day following the institution of streptomycin therapy.

men was checked by nitrazine paper. In most cases this dosage was sufficient to maintain an alkaline urine, but occasionally the daily dosage had to be increased to five teaspoonfuls. In the occasional case with pulmonary or peripheral edema, potassium salts were substituted for sodium citrate.

collate when blood agar or Endo's medium failed to show growth.

All cases were classified as cured, improved or unimproved. Cases in which the original infecting organism disappeared under therapy and for a minimum of one week after all therapy had been dis-

40	Cure	1	4	45	None	Cystitis.
41	Improvement	2	2	23	None	Inhibiting level increased to 2000 microgm. during therapy.

Clean voided urine specimens were obtained daily on male and catheterized specimens on female patients. At the beginning of this study all urine sediments were cultured in sodium thioglycollate in addition to the usual blood agar and Endo's medium. Sodium thioglycollate was chosen, since it has been shown experimentally that this substance, as well as glucose, reduces streptomycin activity.¹⁴ This was soon discontinued, however, since in no case was a positive culture obtained in sodium thiogly-

collate when blood agar or Endo's medium failed to show growth. It was believed that if the urine remained sterile for one week the infection would not relapse, since in the 30 cases considered cured on this basis, there was only one questionable relapse. This case, in which the urine again became positive for *Esch. coli* fifty-six days after therapy had been discontinued, may have represented reinfection rather than an actual relapse. The majority of cases were followed for periods longer than one week (Table 1). No case

was considered cured unless a minimum of two follow-up cultures were done. In most cases, more than two cultures and in some as many as fifteen were obtained over a period of several months. Cases were classified as improved when urine cultures did not become completely sterile, but in which there was a marked reduction in the colony count, as well as improvement in the urinary sediment. Cases were considered unimproved when there was neither clinical nor bacteriologic response to therapy.

The results of streptomycin therapy in 40 cases of urinary-tract infections when classified according to the criteria mentioned above were 75 per cent

respond, whereas another (Case 14) responded to streptomycin after having been infected for fourteen years.

In the improved group of 4 cases, the urine could not be completely sterilized in 2 (Cases 24 and 29), possibly because of the necessity of performing catheterizations every four to eight hours. An additional patient (Case 34) might have been cured had therapy been more intensive and prolonged. In only 1 patient (Case 41) could failure to sterilize the urine be attributed to the acquisition of streptomycin resistance by the infecting organism.

Of the 6 cases classified as unimproved, 3 (Cases 2, 15 and 19) were infected with streptomycin-

TABLE 2 Results of Streptomycin Therapy in Cases with and Those without Urinary-Tract Damage*

Urinary-tract damage	Resistant	4	0	—	0	—	4	100	—

*One patient was probably inadequately treated. Another improved markedly prior to the acquisition of resistance, despite the persistent bacteriuria that continued after the acquisition of resistance; the improvement was maintained during the follow up period.

cured, 10 per cent improved and 15 per cent with no response. Thus, 85 per cent of all cases were definitely aided by streptomycin therapy. These figures indicate that good results may be expected in the majority of urinary-tract infections due to gram-negative bacilli, despite the fact that they have failed to respond to other antibiotic and chemotherapeutic agents. In this study the best results were obtained in cases with no structural damage to the urinary tract in which the infecting organism was sensitive to streptomycin. In this group of 21 cases 91 per cent were cured and 9 per cent improved (Table 2), there were no failures.

Moderate structural damage, such as dilated calyces, slight hydronephrosis, partial stricture of a ureter or small nonobstructing renal calculi, did not seem to preclude a cure if the infecting organism was sensitive (Cases 5, 6, 13, 14, 16, 18, 22, 23, 27, 32 and 39).

Infections with organisms found to have resistance in vitro that was higher than the levels obtained in the urine were unimproved by streptomycin therapy (Cases 2, 15, 19 and 30). One patient (Case 41) in whom resistance was acquired during therapy had shown marked clinical and bacteriologic improvement prior to the development of resistance.

The duration of infection seemed to be of importance only in that it led to marked structural changes and the formation of obstructive renal calculi. One patient (Case 30) in whom the duration of the infection was only eight days, failed to

respond, and in addition there were structural changes in the urinary tract, such as dilatation of the calyces or ureters. Two of these patients (Cases 2 and 19), in addition to harboring resistant organisms and having structural damage, had renal calculi. Only 1 patient with no structural complications (Case 30) failed to respond. This patient was infected with an extremely resistant organism. Failures resulted in 2 patients (Cases 9 and 35) who had streptomycin-sensitive organisms and extensive renal damage as a result of longstanding infection.

Two cases were considered to have relapsed. One of these patients (Case 35) relapsed as soon as streptomycin was discontinued, undoubtedly because of extensive renal damage. In the other (Case 31), relapse after fifty-six days may actually have represented a reinfection.

It is of interest that 1 patient (Case 29) became reinfected with another organism while on streptomycin therapy, but this case required repeated catheterizations, and the reinfected organism was a streptomycin-resistant *Ps aeruginosa*. An additional patient (Case 22), with a partial stricture of the right ureter, was cured of an *Esch coli* infection, but thirty-seven days later became reinfected with *Ps aeruginosa*.

Case 41 deserves special comment. The patient was an eight-year-old child who came into the hospital in a comatose, moribund condition due to a fulminating *Esch coli* pyelonephritis. The nonpro-

tein nitrogen was 165 mg per 100 cc and the blood carbon dioxide 17.2 milliequiv per liter. Because of the marked impairment in renal function sulfonamides were contraindicated, and streptomycin was begun immediately on entry. The urine culture became negative within forty-eight hours, and the renal function began to improve. There is no doubt that streptomycin, in conjunction with fluid and salt replacement, was responsible for saving this child's life.

Nonspecific Urethritis

It appears that at least a portion of cases of urethritis that have previously been considered to be nonspecific, in the sense that they are nongonorrheal and nonpyogenic in origin, are due to infection by organisms belonging to the pleuropneumonia group.¹⁸ On the basis that these organisms are small, gram-negative bacillary forms, it

therapy, there was less dysuria and urgency, the red and white cells in the urinary sediment were markedly reduced, and pleuropneumonia-like organisms could no longer be cultured from the urine. On discharge from the hospital the patient was entirely asymptomatic and remained so during a follow-up period of six months. This infection was of three years' duration, and during that time the patient had never been symptom-free for more than a few days.

The patient in Case 1 received 2.0 gm of streptomycin intramuscularly daily for ten consecutive days. Improvement in urinary symptoms was noted forty-eight hours after the institution of therapy, simultaneously with a marked reduction in the number of red and white cells in the urinary sediment. Pleuropneumonia-like organisms could not be cultured from the urine after the institution of strepto-

TABLE 3 Results of Streptomycin Therapy in Nonspecific Urethritis Apparently Due to Pleuropneumonia-like Organisms

CASE NO	AGE	DURATION OF DISEASE	PREVIOUS THERAPY	STREPTOMYCIN	DOSAGE		RESULT
	yr				DAILY	TOTAL	
					gm	gm.	
1	49	2 mo.	None	2.0	19.2		Cure
2	14	16 yr	Pe icillin and sulfo amide	4.0	26.4		Failure
3	26	3 yr	None	1.0-2.0	13.2		Cure

seemed worth while to try streptomycin therapy, although the sensitivity of the organisms in vitro had not been established because of technical difficulties.

Three cases of infection apparently due to pleuropneumonia-like organisms* were treated with streptomycin (Table 3). One of these cases was a simple urethritis (Case 1), 1 a urethritis associated with prostatitis (Case 2) and 1 a urethritis with hemorrhagic cystitis (Case 3). In all these cases no other micro-organisms could be isolated consistently from the urine. On the other hand, in Case 3 pleuropneumonia-like organisms were isolated from four urine samples, and in Case 2 in five instances from prostatic secretions or urethral discharges prior to the institution of streptomycin therapy. In Case 1 the fact that only one positive culture could be obtained despite repeated attempts is understandable in view of the difficulty associated with the isolation and cultivation of these organisms.

The urine was rendered alkaline in all cases. In Case 3 a total of 2.0 gm of streptomycin was given intramuscularly daily (0.4 gm every four hours, the 2-a.m. dose being omitted). Because of the improvement on the sixth day, the dose of streptomycin was reduced to 1.0 gm daily, and continued for five additional days. Three days after the institution of

mycin therapy symptoms did not reappear during a follow-up period of four months.

In Case 2, a total of 4.0 gm of streptomycin intramuscularly was given daily for eight consecutive days. On the day following the institution of therapy, the urethral discharge disappeared. Pleuropneumonia-like organisms, however, were consistently cultured from prostatic secretions and urine samples during therapy. The urethral discharge reappeared when streptomycin was discontinued.

Haemophilus Influenzae Infections

Four cases of Type B *H. influenzae* infection were treated with streptomycin (Table 4). Two of these were meningitis, and 2 were epiglottitis. In addition to streptomycin the patients with meningitis received sulfadiazine. One patient also received 300 mg of Type B *H. influenzae* antiserum. A Quellung reaction was not obtained, however, with this patient's serum, and it is doubtful whether the antiserum influenced the course of the disease.

Both patients with meningitis received 0.05 to 0.1 gm of streptomycin intrathecally each day, as well as 0.6 to 0.8 gm intramuscularly, divided into six daily doses given every four hours. The spinal fluid in both cases became negative for *H. influenzae* within forty-eight hours after streptomycin therapy had been instituted. Although a bacteriologic cure

*We are indebted to Dr. L. Diffee of the Department of Pathology and Bacteriology, Massachusetts General Hospital, for the isolation and identification of these organisms.

was effected relatively early, clinical response was slower in appearing

Two cases of *H influenzae* epiglottitis requiring tracheotomy were treated with streptomycin. Each patient received 0.2 gm. every four hours intramuscularly. In both cases colonies of Type B *H influenzae* were recovered from the pharynx as well as the blood. The patient in Case 3 received penicil-

were bronchiectasis, 1 a lung abscess, and 1 a case of *Ps aeruginosa* septicemia

The 3 patients with bronchiectasis were treated with streptomycin aerosol. These cases had been treated previously with penicillin aerosol with only slight improvement in the clinical condition. Because they continued to raise large volumes of sputum from which *Esch coli* grew abundantly,

lin and sulfadiazine for two days before streptomycin therapy. Because the temperature remained high, the throat culture remained positive for *H influenzae* and there seemed to be a spread of the pharyngeal infection, streptomycin therapy was started. On the following day the temperature dropped from 104 to 100°F, and *H influenzae* disappeared from the throat culture forty-eight hours after the institution of therapy. In Case 4 strepto-

aerosol streptomycin was believed to be indicated. Doses of 2 cc containing 50,000 units each of combined streptomycin and penicillin were inhaled every three or four hours. When combined therapy was employed the sputum was rendered sterile except for yeasts and fungi. Only 1 of the patients so treated was considered to have been benefited. Although no conclusion can be drawn from such a small number of cases, it appears that combined

mycin was started immediately on entry. Although much more severely ill on admission than the patient in Case 3, this patient had a much smoother convalescence and a shorter period of hospitalization.

MISCELLANEOUS INFECTIONS

Five cases classified as "miscellaneous" were treated with streptomycin (Table 5). Three of these

streptomycin and penicillin aerosol should be given further trial in cases of bronchiectasis.

A case of lung abscess, thought to be due to *H influenzae*, since this organism was obtained in pure culture from the sputum, was treated with combined penicillin and streptomycin aerosol. The sputum was rendered sterile, and in twelve days there was marked improvement in the clinical con-

lition and the abscess cavity was considerably reduced in size.

One case of *Ps aeruginosa* septicemia (Case 5) seems worthy of comment, since in view of the high mortality resulting from such infection, streptomycin is considered responsible for the recovery. (The patient was an eleven-month-old child who had had diarrhea for two weeks and had been treated with penicillin and sulfasuxidine at another hospital. On admission to the Pediatric Service of the Massachusetts General Hospital the temperature was 106°F . *Ps aeruginosa* was cultured from the blood, urine, stool and nasal washings. The patient was given 0.6 gm of streptomycin daily, which gave a blood level of 160 microgm per cubic centimeter. When the resistance of the infecting organism was found to be 16 microgm, the daily dose was increased to 1.2 gm. This dosage gave a blood level of 65 microgm per cubic centimeter. The blood culture became negative on the third day of therapy, and the patient continued to improve. Several days later she developed a scalp abscess from which *Ps aeruginosa* was recovered. In addition to intramuscular streptomycin she received 0.6 gm of oral streptomycin daily, since she continued to carry an abundance of *Ps aeruginosa* in the stools. After the institution of oral therapy, *Ps aeruginosa* as well as *Esch coli* gradually disappeared from the stool.

DISCUSSION

Urinary-Tract Infections

Only a few publications have appeared describing the results of the streptomycin treatment of urinary-tract infections due to gram-negative bacilli. Herrell and Nichols⁶ recorded good results in 10 of 13 cases, whereas Keefer et al.¹¹ reported recoveries in 42 per cent and improvement in 35 per cent of 409 cases. Less favorable results were obtained by Finland and his associates,¹⁴ who observed failures in 8 of 12 treated cases, and Nichols and Herrell,¹⁷ who reported good results in only 42 per cent of cases.

Of the 40 cases of urinary-tract infections reported in this paper, cures were obtained in 75 per cent and improvement in 10 per cent. Since these figures are somewhat higher than those reported in other publications, it seems worth while to compare the method of therapy employed with those used elsewhere. On the basis of the studies of Abraham and Duthe,¹³ in which it was shown that there is a tenfold increase in streptomycin activity when the reaction of the urine is raised from pH 6.0 to 7.5, it seemed desirable to alkalinize the urine in all cases during therapy. In the 12 cases reported by Finland et al.¹⁴ no attempt was made—with a single exception—to render the urine alkaline. Since no mention is made of this in the reports of Herrell and Nichols⁶ and Keefer and his co-workers,¹¹ such an effort was presumably not made. Because the route of administration of streptomycin, the daily dose and the duration of therapy were essentially

the same in this study as those reported elsewhere, the higher percentage of good results is considered to be due to the fact that the urine was rendered alkaline in each case.*

Failure of streptomycin therapy in many cases has been attributed to the rapid development of resistance by the infecting organism. Finland et al.¹⁴ showed that in 8 of 10 cases of urinary-tract infection the rapid acquisition of resistance was responsible for the failure of therapy. It is of great interest that in only 1 case of the 40 reported in this study did resistance develop. The only important difference between the method of therapy employed and those reported elsewhere was the insistence on an alkaline urine in each case during treatment. Accordingly, it seems highly likely that alkalinization is responsible for the failure of the organisms to develop resistance and, as a consequence, for the more favorable results obtained in this study. The mechanism for the failure to develop resistance in an alkaline medium is obscure. It cannot be entirely explained by the greater activity of streptomycin in an alkaline substrate, since in the cases in which the infecting organisms were not completely eliminated no increase in resistance could be demonstrated.

The results of the treatment of urinary-tract infections with streptomycin indicated that urinary levels above the minimal inhibiting dose of the infecting organism must be obtained if success is to be expected. If the minimal inhibiting dose of the organism is higher than the level that can be obtained in the urine, a resistant organism may be said to be present and failure will ensue. The presence of a susceptible organism does not necessarily indicate that a cure will result if marked structural damage is present, but minor and even moderate changes do not necessarily preclude a cure.

In this study it was decided to treat all cases regardless of the initial sensitivity of the organism to determine the relation between action in vitro and clinical response to the drug. Of the 40 unselected cases treated with a daily dose varying between 0.5 and 2.0 gm, 75 per cent were cured and 10 per cent were improved. On this basis it is believed that 2.0 gm of streptomycin daily should produce satisfactory results in the majority of cases. Although the determination of organism sensitivity is desirable before institution of therapy, it is not essential. Since the urine became sterile in 83 per cent of cases forty-eight hours after the institution of therapy, if no clinical response is observed within that time, the sensitivity of the organism should be determined and the dose increased accordingly.

The variations in streptomycin sensitivity among strains of the same organism are well illustrated in

*Since the completion of this paper for publication an article on the favorable influence of alkali in streptomycin therapy of urinary-tract infections by Harris et al.¹⁸ has appeared. In their series of 14 cases 8 were cured. These investigators have noted that the maintenance of an alkaline urine during streptomycin therapy seemed to prevent the infecting organisms from acquiring resistance.

this series. For example, the sensitivity of different strains of *Esch coli* varied from 1.5 microgm (1.5 units) to more than 2.0 mg (2000 units) per cubic centimeter. Other strains of *Esch coli* that were inhibited by as little as 0.5 microgm (0.5 unit) per cubic centimeter have been encountered in this laboratory. In general, the majority of strains of *Esch coli* isolated were sensitive to concentrations of streptomycin that are easily obtainable in the urine, the resistant strains being the exception among this species. Three of the 4 resistant cases (Table 1) were infected with *Esch coli*, whereas another was infected with both *Esch coli* and *Pr vulgaris*. These cases represent only about 10 per cent of all cases from which *Esch coli* was isolated either alone or in combination with other organisms.

It seems to be the consensus that of the gram-negative bacilli, *Ps aeruginosa* is the most uniformly resistant to streptomycin. Two of the four strains of this species, however, encountered in urinary-tract infections were found to be susceptible to fairly small amounts of streptomycin in vitro. These patients were cured of their infections. An additional case was cured, but unfortunately the organism could not be studied for sensitivity in vitro. In view of the clinical response, however, this strain was undoubtedly moderately sensitive, since a rather low daily dose of streptomycin was used. In only 1 of the 4 cases of urinary-tract infection due to *Ps aeruginosa* was resistance in vitro encountered. This case did not respond to therapy. With the exception of Case 2 (Table 1), the strains of *Pr vulgaris* studied were uniformly susceptible to streptomycin.

Because of the marked individual variations among strains of the same bacterial species, the clinical result cannot be predicted solely on the basis of species identification. For example, the infecting organism may be a resistant strain of *Esch coli*, which as a species is considered to be susceptible to streptomycin. Likewise, a given infection may be due to a susceptible strain of *Ps aeruginosa*, which as a species is generally considered to be moderately resistant to streptomycin. Bacteriologic response or sensitivity in vitro should be used as a guide to therapy, the former is perhaps preferable to the latter, since sensitivities in vitro and in vivo are not always parallel.

It might be noted that in mixed infections of Lancefield Group D streptococci (*Str faecalis*) or *Staph albus* and gram-negative bacilli, although streptomycin cleared the urine of the latter organisms, it failed to have any effect on the gram-positive organisms. It is also of interest that in 4 cases *Str faecalis* or *Staph albus* appeared in the urine after therapy was stopped. The majority of Lancefield Group D streptococci studied in vitro were resistant to the streptomycin levels obtained with the dosages used in this study.

Nonspecific Urethritis

Dienes and Smith¹⁹ were able to isolate pleuropneumonia-like organisms from 4 cases of nonspecific chronic prostatitis. More recently, Beveridge et al,²⁰ in Australia, were able to isolate these organisms in 20 per cent of 70 cases of nonspecific urethritis. These workers were unable to find this organism in the normal male urethra. It seems reasonable to assume that pleuropneumonia-like organisms may under certain conditions be responsible for nonspecific urethritis, prostatitis and cystitis.

Because pleuropneumonia-like organisms are small, gram-negative bacillary forms, it seemed worth while to determine the therapeutic effect of streptomycin on cases of nonspecific urethritis and prostatitis from which these organisms could be recovered. In 2 cases, within seventy-two hours of the institution of streptomycin therapy there was a marked decrease in the urethral discharge, as well as a decrease in the number of red and white cells in the urinary sediment. Pleuropneumonia-like organisms could not be recovered after the institution of streptomycin therapy. These patients remained symptom-free for the duration of follow-up periods of four and six months. The third patient appeared to improve while on therapy, but pleuropneumonia-like organisms never disappeared and a relapse occurred when therapy was discontinued. The disappearance of the organisms in 2 cases simultaneously with the onset of clinical improvement seems to support the bacteriologic evidence that pleuropneumonia-like organisms are responsible for certain cases of nonspecific urethritis, prostatitis and cystitis. Since the pleuropneumonia-like organisms probably do not constitute a homogenous group, the success or failure of streptomycin therapy depends in part on the susceptibility of the infecting organism. The failure of Case 2 to respond may have been due to the fact that the patient was infected with a resistant strain.

H Influenzae Infections

Two patients with Type B *H influenzae* meningitis treated with streptomycin recovered. In addition to streptomycin, both received sulfadiazine. One patient also received two doses of specific antiserum. Since a *Quellung* reaction was not obtained with serum from this case, it is doubtful whether the antiserum contributed to the recovery. In both cases the organisms disappeared from the spinal fluid after forty-eight hours of therapy.

The good results obtained in these 2 cases are similar to those reported by others in which antiserum was not used.^{10, 11, 21} A recent report by Alexander et al,²² however, indicates that the severer cases of *H influenzae* meningitis may require specific antiserum in addition to streptomycin and sulfadiazine.

Two cases of *H. influenzae* epiglottitis requiring immediate tracheotomy were treated with streptomycin. In addition, 1 patient received penicillin and sulfadiazine for two days before the institution of streptomycin therapy. Streptomycin was given in this case because throat cultures remained positive for *H. influenzae* and because there seemed to be a spread of pharyngeal infection. Forty-eight hours after streptomycin therapy had been started, the temperature had dropped considerably and *H. influenzae* disappeared from the throat. The other case, in which streptomycin therapy was started immediately on admission, had a much smoother and a shorter convalescence. These results indicate that streptomycin is a valuable adjunct to the treatment of *H. influenzae* epiglottitis.

Miscellaneous Infections

Three cases of bronchiectasis, whose sputums contained gram-negative bacilli predominately, were treated with streptomycin aerosol. All patients had previously been treated with penicillin aerosol with only slight clinical improvement prior to therapy with combined streptomycin and penicillin aerosol. In 2 cases *Esch. coli* disappeared from the sputum within four days of the institution of combined therapy. It is of interest that repeated sputum cultures failed to grow anything other than a few colonies of *Monilia* during and for some time after combined aerosol therapy. In both cases the sputum was reduced somewhat in volume, but in only 1 was there a simultaneous improvement in the clinical condition. In the third case, although there was a reduction in the number of colonies of *Esch. coli*, there was no diminution in the volume of sputum, nor was there any improvement in the patient's condition. These results indicate that although the sputum may be rendered sterile, clinical improvement may not ensue. This raises a question regarding the significance of the presence of *Esch. coli* in the sputum in bronchiectasis. In certain cases the organism is undoubtedly responsible for a low-grade infection, whereas in others it may simply be a commensal saprophyte. In the former case streptomycin therapy may prove to be of definite value, whereas in the latter, although *Esch. coli* can be eliminated from the sputum, clinical improvement may not follow.

One case of postoperative lung abscess believed to be due to *H. influenzae* was treated with combined streptomycin-penicillin aerosol. Previous to the addition of streptomycin, penicillin aerosol alone was used without improvement in the patient's course. After the institution of combined therapy, *H. influenzae* disappeared promptly, and there was a simultaneous reduction in the volume of sputum. The patient improved, and the abscess cavity was reduced in size. This case is still under observation.

Reactions

Eight of the 52 patients treated (15 per cent) experienced reactions that were considered to be due to streptomycin. These were relatively unimportant, and in most cases therapy was continued despite these manifestations. One patient complained of headache and vertigo, and 2 of pain at the injection site. Another developed a febrile reaction, and skin eruptions were observed in 4. The latter took the appearance of a papular, erythematous eruption that was somewhat pruritic. Three of the 4 patients who developed skin manifestations were children who, because of their small size, received a relatively larger dose than the adults.

SUMMARY

Thirty-eight cases of pyelonephritis and 2 of cystitis due to gram-negative bacilli were treated with streptomycin. Cure was effected in 75 per cent, and improvement in 10 per cent, and 15 per cent failed to respond. Despite moderate renal damage and the presence of small nonobstructing renal calculi, cure resulted if the infection was due to a susceptible organism.

Patients infected with organisms with resistance in vitro greater than the levels that could be obtained in the urine with the dosage used in this study failed to respond. The acquisition of resistance by the infecting organism was not responsible for the failures reported. An appreciable increase in resistance was observed in only 1 case.

Two of 3 cases of nonspecific urethritis in which only pleuropneumonia-like organisms were isolated responded clinically and bacteriologically to streptomycin therapy.

Two cases of *Haemophilus influenzae* meningitis responded well to streptomycin therapy.

Recovery in 2 cases of *H. influenzae* epiglottitis seemed to be hastened by streptomycin therapy.

The favorable outcome in 1 case of *Pseudomonas aeruginosa* septicemia was undoubtedly due to the prompt use of streptomycin.

Of 3 cases of bronchiectasis in which *Escherichia coli* was the predominating organism in the sputum, only 1 showed clinical improvement as a result of treatment with combined penicillin and streptomycin aerosol.

One patient with lung abscess thought to be due to *H. influenzae* seemed to improve on combined penicillin and streptomycin aerosol.

Minor toxic reactions were observed in 15 per cent of cases.

MEDICAL MOTION PICTURES IN PRIVATE PRACTICE*

DONALD W LEONARD, M D †

EXETER, NEW HAMPSHIRE

PRIVATE practice, especially in rural communities, often makes an active physician believe that he is no longer practicing scientific medicine. He must fight the impression that the distance between him and the nearest medical center is directly responsible for the distance he seems to be from ever producing anything of value to medical science. When faced with the reality of a patient at home, he is sure to remember the skillful correlation of x-ray, laboratory and clinical facts that gave him such pride as an intern and to feel dismayed at the seeming hypocrisy of entering a private home to undertake treatment with no support beyond his own unaided judgment. Sooner or later, however, he will meet a new situation that would not have been possible in his beloved hospital, and some makeshift surgery or substitute drug will produce surprising results. With this will come the realization that his everyday work is actually a series of medical studies, and the success of his extemporizing will give him the comforting assurance that he has used originality equal to any that his former classmates could have shown in their research laboratories. This realization will bring a desire to share the observation with other

physicians. The private practitioner will then need a medium of expression that has not been rigidly standardized but has concrete value as a presentation of the patient, even though it is technically incomplete because of its lack of bibliography, tabulated data and controlled experimentation. Amateur motion pictures will provide him with such a medium, and it is the purpose of this discussion to present evidence that the technics of motion-picture photography on medical subjects are well within the scope of a private practice.

Everyone has enjoyed motion pictures made by the popular producers in Hollywood. All of us are somewhat acquainted with the lusty offshoot doing profitable service in business advertising. Every physician has seen some of the films prepared in the large hospitals and clinics and having to do with operative surgery, medical education or public health. None of us have become sufficiently acquainted in a medical way with the humble amateur following his hobby in his own narrow circle but fully capable of producing pictures of professional clearness. Many a physician has been portraying the affairs of his own family but, with equipment right at his elbow, has never turned his hobby toward his medical work to discover how much it can enliven his practice with pictorial records of unusual cases. With the aid of motion pictures, a case history becomes an epic for demonstration at a medical meeting. To produce these films, the private practitioner needs information and gentle persuasion to convince him that motion pictures can be taken of his medical curiosities with equipment that does not require a studio and does not concern itself with darkrooms and film processing,

*An inquiry among active members of the New Hampshire Medical Society early in 1947 disclosed the following figures from the first two hundred replies: owners of motion-picture cameras 65 (32.5 per cent), with 16 who had taken films of patients and 8 who had asked others to take pictures; physicians who did not own motion-picture cameras numbered 135 (62.5 per cent); those who had taken pictures with cameras belonging to others, 20; and those who had asked others to take pictures, 13. Potential motion-picture makers thus numbered 98, or 49 per cent of physicians who made replies.

Relatively few of the physicians in this "interested group" are specialists or are associated with clinics having photographic departments. It therefore seems that clinical motion-picture records in private practice should be emphasized as a practical development of this interest.

†Member, active staff, Exeter Hospital.

except in the remote headquarters to which he mails the film carton

SUBJECT MATTER

The physician who wishes to record his experiences must not forget to make his sequence of pictures logical and systematic so that the interest of his audience will not be lost. Certain limitations in the choice of subject matter can wisely be observed. Subjective symptoms will give no pictorial impression, and the sickest patient will look at ease on the screen unless he is evidencing his inward discomfort by attitude, gesture or grimace. Records of most of the abdominal emergencies will be limited to pictures of the actual surgical procedures. Growths and external anomalies will lend themselves well to views before and after treatment. Fractures will have no pictorial significance unless there is obvious deformity or a well explained series of x-ray studies, although the technic of reduction and the apparatus for fixation will be excellent for the film record. Many of the limitations can be overcome by diagrams and charts, which are incorporated in the finished series of otherwise disjointed pictures.

Motion is the essence of this type of pictorial recording. It is almost too obvious to note that the presence of motion is the factor that gives medical motion pictures superiority over still pictures when the restoration of a function or an alteration of gait is a vital sign of clinical progress. If wanted, still pictures can be made by the thousand from the motion-picture film by the simple process of enlargement of single frames.

The private practitioner may carry out his medical filming along several lines, which may merge at many points. He may begin by taking pictures of all sorts of interesting cases and putting them all in a "medical scrapbook." Such views taken at random will often include different stages of progress in the same patient, and these can be removed from the collection to be spliced together with a few diagrams and explanatory titles to make a complete case record. A little planning in a case that promises interesting developments will usually result in a better medical thesis because it will be possible to arrange visual emphasis by comparisons with a normal and by the inclusion of extra pictorial data on tests that might not actually be required by the treatment. The medical motion-picture maker must be guided by foresight into the reactions of his future medical audience, and he must be bound by a self-imposed law that the material has to be of clinical importance and has to be presented in a colorful but still accurate manner.

Even though the private practitioner may not include in his daily work any actual surgery, he will occasionally be interested in following a case through the operating room. He will probably do this repeatedly in the same hospital and from

experience learn the specific lighting conditions and the facilities for picture taking. Surgery offers the most spectacular but also the most exacting field for the amateur movie maker. Since the type of disease involved determines whether or not the procedure is suitable for pictures, the photographer must have the co-operation of the surgeon and must be ready to abandon his plans when there is deep dissection within the abdomen or in any similar cavity. Motion pictures under these conditions are beyond the reach of the usual amateur, and the procedures can be much better demonstrated by diagrams. Among the most favorable surgical subjects for motion-picture photography in the operating room are amputations, excisions of large tumors, plastic operations and others with similar obvious surface details. No better scenario was ever written than a cesarean section.

TECHNIC

No one can talk about taking pictures of any kind without dwelling on the subject of exposure. For the motion-picture maker this detail has been reduced to a single step completed by setting of the size of the opening in front of the lens. The other camera factors remain standard because of their fixed relation to the speed of the action and of future projection. On most cameras there is a dial for setting the diaphragm according to the amount of light falling on the subject under conditions described in words that have been etched on a plate or printed card attached near the lens mount. The photographer must judge the suitable point according to these descriptions and set the aperture at the corresponding figure. The same figures are used in the directions that come with the film and with such accessories as photo-flood lighting units and title holders. With certain types of lighting and in definite places the motion-picture maker will discover that with his camera no satisfactory picture can be taken without artificial lighting or by moving of the subject into a better light. He will do well to learn early that an improperly exposed strip of film spliced into the finished film will spoil the effectiveness of otherwise excellent exposures.

Absolute rock-like steadiness of the camera while pictures are being taken is essential. Rapid swinging of the camera and even the small undulations caused by excited breathing will produce a giddiness that is distressing. Swinging of the camera during the taking of pictures is permissible only when there is a steady following of a moving object that itself retains a relatively fixed position in the frame of the picture or when slowly "tilting" or "panoraming" toward the center of interest across features of the scene that have such important bearing that they cannot be shown effectively in separate views. Thus, a close view of a patient with extensive edema can be obtained by moving slowly from the swollen feet to the region

of the face. A tripod is the standard means of securing steadiness for the camera. Other commercially made gadgets are available, but even without these assistants it should be possible for the photographer to hold the camera firmly enough in his hands and against his cheek regardless of the position of his body. In this manner, he can be sure of the greatest possible freedom to make quick changes in angle or position.

Lighting problems are quickly solved by photo-flood bulbs. With these as a source of light, it is naturally easier to be sure of the proper exposure if there is no additional, unmeasured light from the sky. In medical filming the background is usually without special interest so that its loss in the dark shadows beyond the radius of effective artificial lighting can give the subject a detached importance that will compare well with views taken in other rooms and on other occasions. Instructions with the lighting units are sufficient for the determination of the aperture in relation to the number and distance of the lights from the subject. All types of panchromatic black-and-white film register correct color values with this illumination, but color photography under the same circumstances demands a special type of film that is balanced for artificial light and sold for this purpose.

In attempting to take motion pictures indoors by natural light the value of "top light" must be appreciated, its absence in any room that is without large windows makes this type of motion-picture photography extremely unsatisfactory. A few older hospitals still have top-floor operating rooms beneath skylights, but the good north light that these have been planned to provide will give the only favorable conditions that one can ever expect to find for indoor natural-light photography. There may be a temptation to use direct sunlight for indoor photography, but it must be remembered that sunlight through the limited area of a window sash will give lines of shadow from the window frame and contrasting light and shadow on the subject with a spotlight effect unless something is done to lighten the shady side.

Greater interest in medical motion pictures is created by a change in the camera angle for variety. This does not refer to camera angles that distort perspective or overemphasize certain characteristics because it is imperative that medical motion pictures avoid "trick photography" and retain scientific accuracy. There is, however, no reason for the monotonous use of eye-level views when the camera man can walk around the patient to take successive views just as a visiting physician would do if he were given the same opportunity. Variation of the angle and position of the camera in this manner will make the film record more human and natural for the future edification of a medical audience.

A sprinkling of close-up views will also give greater satisfaction when associated with more

distant views of the whole subject. There is never a general view that does not contain a center of interest made so by its own arresting nature or by the subject of the demonstration. As soon as it is apparent that the audience will want to examine more closely, it is wise to be able to splice in a satisfactory close-up to show the details. The camera will then have done just what the average physician would have done if he had been in the presence of the patient. This feature may make the difference between success and failure when it comes to holding the attention of a medical audience.

The amateur camera man should be certain that the lighting, the camera angle and the distance from the subject are such that the picture recorded will show what is intended. It is obvious that the important part of the subject should be in the frame of the picture and not unintentionally cut off by one of its margins. This calls for reasonable care in framing the view accurately in the finder. This is more exacting with close-ups. If a view is intended to show a localized swelling, depression or pulsating blood vessel, there should be sidelighting to bring out the contour by a delineating shadow. These things may make necessary the moving of lights or the assumption of some odd position by the photographer but the results will be worth the trouble. Finally, it is suggested that the whole matter of picture taking be considered an art in itself and that the proportions of foreground, background and object of interest of each frame, as well as can be accomplished under conditions often too rigid to change, be artistically balanced, so that a degree of "finish" may be apparent in the completed film.

EDITING AND TITLING

The step in the production of a medical film known as "editing" represents the carrying out of a plan that governs the selection of titles and the arrangement of film strips that may have been taken at widely separated occasions. The mainstay of the film editor is the process of film splicing. This step, whether done by hand or with one of the mechanical splicers, consists essentially of cutting the film ends, scraping away the emulsion and cementing the prepared ends together so that the sprocket holes on the margins of the film form a continuous series properly spaced. Each film editor in the amateur field can choose a plan that is entirely his own, but he may profitably copy many of the methods of cutting that he has observed on the professional screen. In medical pictures the emotional values are not of primary importance so that the continuity of the film story need not follow the standard paths of medical reasoning, demonstrate or teach, holding the interest of the audience by the substance of the material rather than by the ingenuity of the producer. Editing should, however, strive to satisfy the medical

curiosity of future audiences. If the editor believes that this curiosity demands a close view, he should supply it, if it seems likely that a member of the audience unfamiliar with the material will want an explanation, he should place a title or a diagram at that point. Enough clinical data should be included in some manner along with the pictures to forestall any impression that the presentation is pointless. This all implies that the grouping of subjects should be tied together by a single theme either in the form of a discourse on one malady or as a frank presentation of the miscellaneous contents of a movie "scrapbook."

All films should be titled and edited before being shown to anyone except an occasional person who may have a direct interest in the care of the case. Complete editing means also that the material has been assembled according to plan, with the elimination of all unfit film as judged by any of the standards thus far discussed. Titling means the addition of written material or diagrams to supplement the pictures and round out the production into an understandable silent motion picture.

PROJECTION AT MEDICAL MEETINGS

Projection of medical motion pictures made by the private practitioner for his medical associates represents the goal of the entire endeavor of their making. The finished film, deftly shown to a comfortable audience, gives the hobby its greatest justification, but this seemingly simple matter has its problems and an excellent film may be made less effective by bad conditions at the time of projection. The medical photographer will probably find that in his locality the audiences made up of his professional colleagues will be of about the same size each time they gather. The size of the group and the room in which the pictures are shown may therefore become familiar factors. In an informal group it always pays to ask certain members to move into positions between the projector and the screen before the film begins, and it is better, if possible, to have the screen only slightly above natural eye level, even if it is necessary to provide a center aisle. The carrying case of the projector may sometimes serve as a stand for the machine to bring it that much higher than the ordinary table top so that the rays of light will hit the screen at right angles to its surface. The distance should be so adjusted that the picture will completely fill the reflecting surface within the black borders of the screen without overlapping onto the wall behind.

Although the room for projection must be darkened in some way, it is recognized that absolute darkness is usually unnecessary. Unavoidable sources of light should be shielded from the eyes of the audience, and beams of light must be prevented from hitting the screen to give unequal illumination of the darker parts of the pictures. When color film is shown, it is wise to have less light in the room and to be sure that what little remains is without decided color of its own to unbalance the colors in the pictures.

As pointed out above, if the medical motion-picture maker wishes to establish and preserve a reputation, he must consistently refrain from showing his pictures until completely prepared for projection. He should never be forced to provide running comment to explain his continuity or excuse defective photography unless he plans to have someone read a prepared script through a microphone to simulate a sound film. His handling of the projector should be quiet and not accompanied by false starts, flashes of light, delays or rewinds. He can accomplish a smooth beginning by starting the motor of the projector before turning on the light as the first title appears, and make a graceful ending by turning off the light before the blank strip runs through to give a haze of light on the screen. The exhibitor should try to have his machine as quiet as possible by proper oiling, by straightening bent reels and by the use of a rubber pad under the machine if it is necessary to absorb the vibration. His table for projection should be solid, his electrical connections tight, and his projector gate and lens clean, and he should have everything in readiness before his audience arrives. All this care for detail will reap dividends in satisfaction, and an already theater-minded audience will wonder how an amateur could obtain such pictures.

SUMMARY

The groundwork for the production of creditable medical motion pictures by the private practitioner is discussed. The fact that motion pictures, as a field of medical expression, fall easily within the scope of a private practice is stressed. Any physician with simple equipment may obtain and use motion pictures to record his unique cases, because he has in his private practice the one vital thing necessary for such a visual record—the patient himself. No clinic or hospital has more than that.

of the face. A tripod is the standard means of securing steadiness for the camera. Other commercially made gadgets are available, but even without these assistants it should be possible for the photographer to hold the camera firmly enough in his hands and against his cheek regardless of the position of his body. In medical pictures the emotional values are not of primary importance, so that the continuity of the film story need only follow the standard paths of medical reasoning to demonstrate or teach, holding the interest of the audience by the substance of the material rather than by the ingenuity of the producer. Editing should, however, strive to satisfy the medical

Physical examination was essentially unchanged. Complete ophthalmologic examination revealed no abnormal signs other than those noted and recorded on admission. The total fluid intake and output, which were 2500 and 1148 cc. respectively, continued a normal course throughout the hospital stay.

On the 3rd day the temperature fluctuated between 100 and 104°F and the lower pole of the spleen became palpable. Daily blood smears taken at the peak of the fever and several taken after the administration of 1 cc. of adrenalin revealed no malarial parasites. X-ray studies of the skull and visual field examinations were essentially negative. The white-cell count remained under 10,000, and the differential count was within normal limits. The total serum protein was 6.4 gm per 100 cc., with an albumin of 4.7 gm, the albumin-globulin ratio being 2.8. An agglutination test for *Brucella* organisms was negative, and the results of the heterophil-antibody study were not yet known, the Boce-Jones protelo was normal. Repeated throat smears and culture revealed beta-hemolytic streptococcus and *Staphylococcus aureus*. A blood specimen taken for culture was negative. The blood Kahn test was also negative.

On the 5th day the hemoglobin was 15 gm. per 100 cc. and the white-cell count 6700, the differential count being within normal limits, but an occasional blood cell resembling the lymphocytic series and believed to be a polymorphocyte was seen. A sternal puncture revealed essentially normal bone marrow.

From the 6th to the 15th hospital day the white-cell counts began to rise and fluctuate between 13,000 and 22,150, the differential counts revealing 88 to 98 per cent lymphocytes, 10 or 15 per cent of which were polymorphocytes and 1 or 2 per cent so immature that they were difficult to differentiate from lymphoblasts. At least 5 per cent of the lymphocytes had fenestration and heavy nuclear, chromatin network. The peroxidase stain was negative.

On the 11th hospital day the heterophil antibody titer was 1:448. The blood specimen for this examination had been drawn on the 4th hospital day.

The repeated blood examinations, which revealed the lymphocytosis and fenestrated lymphocytes, the abnormal heterophil-antibody titer, the palpably enlarged spleen, the absence of anemia and the normal bone-marrow study substantiated the diagnosis of infectious mononucleosis.

To aid the patient during the period of extreme lymphocytosis 40,000 units of penicillin was administered every 4 hours, and large doses of components of the vitamin B complex were given orally. Pyridoxine for intravenous use was not available.

The patient continued to run a low-grade intermittent fever, and on the 13th hospital day, while still on penicillin therapy, he developed an acute bilateral, lacunar tonsillitis. The temperature, however, never rose above 100°F. Within

3 days the throat signs and symptoms began to recede, and the temperature returned to normal and remained so until discharge from the hospital.

During the entire hospital stay, the patient was given complete neurologic examinations daily, but no disease other than that noted and recorded on admission was discovered. From the 18th hospital day until the 31st hospital day, the spleen gradually receded in size, until it was not palpable 7 days before discharge. A blood study on the 28th hospital day revealed that the lymphocytes were shifting back toward a normal percentage but were still 69 per cent, the neutrophils 25 per cent, the monocytes 3 per cent and the eosinophils 3 per cent. The papilloretinal edema had almost completely subsided.

On the 31st hospital day the patient was discharged feeling and looking well. The papilloretinal edema had completely disappeared, and the spleen was no longer palpable. The heterophil antibody titer was still 1:448 but the white-cell count was 6000 with 50 per cent lymphocytes and 50 per cent neutrophils, no normal white cells were apparent.

SUMMARY

An unusual case of infectious mononucleosis with a complicating bilateral papilloretinal edema is presented. The history and physical findings suggested a variety of conditions, but the laboratory data and the course confirmed the proper diagnosis.

MEDICAL PROGRESS

SERUM LIPIDS AND THEIR VALUE IN DIAGNOSIS (Concluded)*

SIEGFRIED J THANNHAUSER, M D †

BOSTON

Normocholesteremia and Foam-Cell Formation

Increased xanthoma formation in essential xanthomatosis of the normocholesteremic type This condition is synonymous with Schüller-Christian disease, lipid granulomatosis, eosinophilic granuloma and eosinophilic xanthomatous granuloma. Pinkus and Pick^{87, 88} were the first to discover that the fat substances in the foam cells are cholesterol and cholesterol esters. These authors advanced the theory that cholesterol infiltration of certain cells takes place because of an increased cholesterol supply from the blood. In the syndrome under discussion, xanthoma-cell formation occurs without increased cholesterol supply from the blood — that is, with normal cholesterol values in the serum. Waldeyer⁸⁶ has already suggested that the xanthoma cell is an embryonal cell capable of forming different kinds of lipids, which are retained within the cell and released only by disintegration of these cells. Since reticulum cells and histiocytes may retain the functional possibilities of embryonal cells, it can be assumed that they are also capable of forming various kinds of lipids including cholesterol. It is conceivable that in these cells an inherent metabolic potentiality or a disturbance of the intracellular enzymatic systems concerned with the formation of cholesterol results in an accumulation of cholesterol within the cells, thereby transforming them into xanthoma cells (foam cells). It may be understood that under these abnormal conditions the excess of cholesterol found is retained within the cell and is not released into the blood stream. Such an explanation was applied by Thannhauser and Magendantz^{43, 44} to the pathology of a systemic disorder showing xanthomatous and granulomatous features, which they designated as "primary essential xanthomatosis of the normocholesteremic type," singling out the normal cholesterol content of the serum as the leading clinical sign for differential diagnosis.

It was emphasized by these authors that certain organs may be involved singly or in various combinations in this systemic disease. The organs that may be affected are the skin (disseminated type of xanthomas), osseous system, dura, brain, lungs, pleura, liver, spleen and lymph nodes.^{43, 44} Involvement

of the dura, brain and osseous system is known as Schüller-Christian syndrome.⁸⁹ Rowland,⁹⁰⁻⁹² Chester⁹³ and Fraser,⁹⁴ in their pioneer work on the histology of the xanthomatous lesion in Schüller-Christian syndrome, had already demonstrated clearly that this lesion is granulomatous in nature (lipid granulomatosis). The presence of numerous eosinophils, as well as histiocytes and reticulum cells, in the granulomatous tissue had already been observed by these authors. These early investigators were, however, more impressed by the nests of foam cells in the granulomatous lesions than by the eosinophils and histiocytic elements and therefore designated the lesions as "xanthomatous" and the disease as "lipid granulomatosis" or "cholesterol granulomatosis." Ceelen,⁹⁵ in 1933, and Gerstel,⁹⁶ in 1934, suggested that the systemic granulomatous process is the primary feature of the disease, whenever foam cells appear in later states. In 1940 Lichtenstein and Jaffee⁹⁷ reported cases of solitary bone lesions of this disease. Fraser⁹⁴ had previously published cases with solitary bone lesions in an excellent and detailed study, describing and picturing the main histologic features of the lesions — namely, the reticulohistiocytic proliferation, the increase of eosinophilic cells in the granulomatous tissue and the gradual development of foam cells in the lesion. He designated such bone lesions as "lipoid granulomas." Lichtenstein and Jaffee apparently believed that this type of granuloma was a disease not hitherto described and named it "eosinophilic granuloma." It was not until the studies of Farber⁹⁸⁻¹⁰⁰ and Engelbreth-Holm, Teilum and Christensen¹⁰¹ that the designation "eosinophilic granuloma" was applied not only to single bone lesions but also to those of the Schüller-Christian syndrome, as well as to the generalized lesions in other organs of the group clinically classified by Thannhauser and Magendantz⁴³ as "essential xanthomatosis of the normocholesteremic type." Through the studies of Teilum and his co-workers it was histologically demonstrated that the natural history of such an eosinophilic granuloma comprised the following different phases: a proliferative phase in which reticulohistiocytic proliferation associated with accumulation of eosinophilic leukocytes is observed — in this phase there is no evidence of foam cells, a granulomatous phase, with increase of blood vessels and fibrils, reticular cells and histiocytes, eosinophils and giant cells (Touton cells) and incipient lipid phagocytosis, a xanthomatous phase,

with nests and isolated foam cells, and a fibrous stage, considered to be evidence of healing. These four phases often show no strict demarcation during the course of the disease, and their histologic features may overlap considerably during the course of the disease. The paper of Lichtenstein and Jaffee¹⁷ has caused considerable misunderstanding about the classification of the disease under discussion, as is obvious from recent publications such as that of Weinstein and his associates.¹⁸ It is evident that solitary eosinophilic granuloma is the monosymptomatic early stage of a systemic disease designated by Fraser¹¹ and Chester¹² as lipid granulomatosis, by Rowland¹⁰⁻¹² as Schuller-Christian disease and by Thannhauser and Magendanz,^{13, 14} from the clinical point of view, as essential xan-

thomatous increase of the normal constituents of this tissue, presupposing that a large specimen of this organ is used for the quantitative chemical analysis. For this reason, the quantitative analysis of a tissue specimen will not show a considerable increase of cholesterol originating from detritus of microscopic areas of focal necrosis, since the increase of cholesterol in one cell is balanced by the loss of cholesterol from another cell, which has previously undergone dissolution.

The quantitative chemical analysis of 0.5 to 2 gm of tissue in the xanthomatous phase of eosinophilic xanthomatous granuloma shows an increase of ten to twenty times in the quantity of cholesterol as compared with the content of a piece of normal organ of similar weight. These

TABLE 3 Lipid Partitions in Specimens of Tissue during the Xanthomatous Phase of Eosinophilic Xanthomatous Granuloma.

Tissue	TOTAL CHOLESTEROL %	FREE CHOLESTEROL %	CHOLESTEROL ESTERS %	TOTAL PHOSPHOLIPID %	SPHINGO- MYELIN %	LECITHIN	TOTAL FATTY ACID	NEUTRAL FAT
Diseased lymph node ¹	17.90	2.20	15.70	6.4	Trace	—	—	—

thomatosis of the normocholesteremic type. All these authors refer to the same disease. The designation of the disease in question as eosinophilic xanthomatous granuloma satisfies the clinical and the histologic observations, even if such a classification does not embrace the proliferative reticulohistocytic phase.

The recent histologic studies of Farber¹⁵⁻¹⁰⁰ and especially of Teilmann¹⁰¹ contributed to a better understanding of the histology of the lesion. There is, however, an important point in which one may differ from the interpretation of Farber,¹⁵ who does not regard xanthoma-cell (foam-cell) formation as one of the pathognomonic features of the lesion. He implies that the xanthoma cell, if present in the granulomatous tissue, develops by cholesterol infiltration into the cells. Cholesterol should originate from the detritus of focal necrosis and should be locally absorbed and stored by the macrophages. The following objections may be raised against this interpretation.

A considerable increase of a normal chemical constituent of a tissue can be the result of an infiltration of this substance into the cells due to an increased supply from the blood stream or of an increased formation of this substance within the cells of the tissue. A shift of a chemical cellular constituent from one cell, which has supposedly undergone dissolution, to another cell macrophagic in character will not cause a meas-

urable increase of the normal constituents of this tissue, presupposing that a large specimen of this organ is used for the quantitative chemical analysis. For this reason, the quantitative analysis of a tissue specimen will not show a considerable increase of cholesterol originating from detritus of microscopic areas of focal necrosis, since the increase of cholesterol in one cell is balanced by the loss of cholesterol from another cell, which has previously undergone dissolution. The enormous increase of cholesterol in the analyzed specimens of tissues during the xanthomatous phase of eosinophilic granuloma must originate in the organ itself as a result of increased cholesterol formation within certain cells capable of cholesterol synthesis. These cells, mostly of reticular and histiocytic origin, form and retain cholesterol, gradually developing the features of foam cells. The data presented in Table 3 illustrate this interpretation.

Xanthoma disseminata of the skin, the lesion characteristic of this group of xanthomatous granuloma, does not undergo visible necrosis, and microscopical examination reveals no extensive foci of necrosis, which could explain the extensive development of foam cells in the lesion.^{101, 102}

Granulomatous lesions of the skin—like those in Hodgkin's disease, mycosis fungoides and infectious granuloma—show large areas of necrotizing processes even with macroscopically visible ulceration but no foam-cell formation. It is not understood why foam cells should arise only from the detritus of cells in eosinophilic

xanthomatous granuloma when they do not originate from the detritus of other granulomatous lesions in which large areas of necrosis are present. It is therefore unlikely that xanthomatous cell formation in the xanthomatous phase of eosinophilic xanthomatous granuloma is an accidental occurrence originating from the debris of local necrosis. It is, rather, suggested that during the abundant proliferation of reticulum cells and histiocytes in the earlier phases of the disease, cells that have preserved the inherent ability of the embryonal reticulum fat cell to synthesize and retain cholesterol within the cell arise and thus develop in a later phase into xanthoma cells (foam cells).⁶⁶

Farber⁹⁸ states that he is not willing to accept the classification of Schüller-Christian syndrome in the group of lipid metabolic disorders. One can only agree with this consideration so far as this syndrome is not caused by a general disturbance of the *intermediary* cholesterol metabolism. For the consideration discussed above, it may be assumed that in the course of granuloma formation in the disease under discussion cells mainly of reticular and histiocytic origin intrinsically accumulate cholesterol as a result of an inherent metabolic potentiality or an intracellular metabolic disorder. These cells, which gradually develop the features of foam cells, are as pathognomonic in the later phases as the accumulation of eosinophilic cells is in the early stages of the disease. The evidence at present points to a formation of cholesterol within the cell rather than cholesterol infiltration for the explanation of the mechanism of xanthoma-cell formation in eosinophilic xanthomatous granuloma. For clinical considerations, however, the normal cholesterol content of the serum in this syndrome is an important feature for the differential diagnosis from other types of xanthomatoses.

Local accumulation of foam cells. A local accumulation of foam cells is occasionally encountered in inflammatory tissue or in a tumor growth, as in osteomyelitis, osteitis fibrosa, cystica disseminata, xanthomatous transformation of the mesentery and xanthoma cells in tumors. The serum cholesterol in such cases is normal. The mechanism of an occasional foam-cell development in a local, small, well defined area is not yet clarified.

LABORATORY PROCEDURES

The extraction of serum or wet tissue, according to Bloor,¹⁰⁶ is the basis of the determination of the total lipids and of the lipid fractions. This precedes all other analytic procedures. In the method for the determination of the total phospholipids the alcohol-ether extract is evaporated to dryness under reduced pressure or in an atmosphere of nitrogen, the dry residue is extracted with a small amount of petroleum ether from which the phospholipids can

be precipitated by acetone and magnesium chloride and determined oxydometrically after treatment with chromic acid. In this laboratory we prefer to determine the total phosphorus directly in the petroleum ether extract because the results obtained with this technic are not influenced by the presence of cerebrosides. Gortner¹⁰⁷ also concludes that the results obtained with phosphorus determination are more consistent than those obtained with the oxydometric methods.

Folch and Van Slyke¹⁰⁸ described a different extraction procedure for the plasma lipids by which certain disadvantages of Bloor's procedure, such as the contamination of the final petroleum ether extract with nonlipid substances, can be avoided. The lipids are precipitated together with the proteins by colloidal iron in the presence of magnesium sulfate. Finally, they are extracted from the washed precipitate by an alcohol ether mixture at room temperature. In the event that one wishes to determine the lipids and their fractions in dry tissue, small pieces of the fresh material are immersed in ether cooled with solid carbon dioxide. The frozen pieces are dried in a vacuum desiccator over phosphorus pentoxide.

Various analytical procedures for the quantitative estimation of the phosphatide fractions have been devised. When they are combined with the determination of the total phospholipids, a fairly complete quantitative partition of a given phospholipid mixture is obtained. It should be pointed out, however, that the results obtained with different schemes of the partition show some discrepancies that cannot yet be completely explained. One of the difficulties encountered in this field arises from the necessity of hydrolyzing the lipids prior to the chemical analysis. Despite the fact that the general behavior of the lipids toward hydrolyzing agents is fairly well known, the conditions required for the quantitative hydrolysis of individual components of the various fractions have not as yet been studied sufficiently to exclude errors due to incomplete hydrolysis.

Phospholipids

The amount of amino nitrogen in phospholipid mixtures corresponds to the total amount of cephalins. The Van Slyke method is therefore widely used for the determination of cephalin in phospholipid mixtures. It must be emphasized, however, that unsaturated fatty acids evolve considerable amounts of inert gas with nitrous acid.¹⁰⁹ Folch, Schneider and Van Slyke¹⁰⁹ found negligible amounts of cephalin in the serum lipids when they took the precaution of hydrogenating the lipids before the determination of the amino nitrogen. Entenman and Chaikoff¹¹⁰ obtained similar results by means of choline determinations in the plasma lipids. It appears that amino nitrogen determinations in the lipid mixtures should be carried out after the

Removal of the fatty acids by a suitable method of hydrolysis

A micromethod for the determination of the two known component nitrogen groups of cephalin — namely, ethanolamine and serine — has recently been reported by Artom.¹¹¹ It is based on the quantitative liberation of the nitrogen of either substance in the form of ammonia during the oxidation with periodate. When this method is combined with the quantitative separation of both substances by the selective adsorption of colamine on permute, the amounts of either substance can be determined. In many tissues the sum of ethanolamine and serine as determined according to Artom's method agrees with the values for the total cephalin obtained by other methods. In some organs, such as the brain, kidneys and lungs, the figures obtained with the periodate method are too high, probably owing to the presence of sphingolipids in considerable amounts. It should be mentioned that Artom found considerable amounts of cephalins in blood plasma, contrary to the results obtained with some of the techniques reported above. Blix¹¹² estimated cephalin in determining choline in hydrolysates of phospholipids by vacuum distillation under a pressure equivalent to 10 mm of mercury at 75 to 80°C and following acidimetric titration.

The sum of the choline-containing phospholipids (lecithin and sphingomyelin) can be estimated by the determination of the choline obtained after refluxing the lipid mixture for two hours with saturated barium hydroxide.¹¹³ The best method for the determination of choline appears to be the spectrophotometry of its reimeckate in acetone solution.¹¹⁴ Amounts between 50 and 400 microgm can be determined with an error of 5 per cent.

Taurog and his co-workers¹¹⁵ achieved the separation of the choline-containing from the noncholine-containing phosphatides of liver by adsorption of the total phosphatides on magnesium oxide and selective elution of the choline-containing phospholipids by methanol.

The sum of the glycerol-containing phosphatides (lecithin and glycerol cephalins) is obtained by glycerol determinations in the dried phospholipid fractions, according to Blix.¹¹⁶

Attempts have been made to determine the glycerol in lipid extracts by periodate oxidation.¹¹⁷ The application of this principle to the analysis of fats appears to give reliable results. In the analysis of phospholipids, the use of periodate for the analysis of glycerol encountered two serious difficulties: the presence in the hydrolysate of interfering substances such as colamine and serine and the fact that the usual procedures for the hydrolysis of phospholipids do not lead to the liberation of glycerol as such but to the formation of a mixture of alpha and beta glycerophosphoric acid, the latter not reacting with periodate and thus escaping determination. It should be emphasized that

alpha and beta glycerophosphate, rather than glycerol, should be used as test substances whenever procedures for the determination of glycerol in phospholipid mixtures are to be checked.

A convenient micromethod for the quantitative partition of phospholipid mixtures into monophosphatides and sphingomyelin has been developed by Schmidt et al.¹¹⁸ When lecithin or cephalins are incubated with nitrogen and potassium hydroxide at 37°C. for fifteen hours, the total amount of their phosphorus groups become soluble in dilute acids, whereas the phosphorus of sphingomyelin remains insoluble under these conditions.

A direct microdetermination of sphingomyelin as acetone-insoluble reimeckate has been described by Thannhauser, Benotti and Reinstein.¹¹⁹ The sphingomyelin reimeckate includes that of hydrolecinithins, which have recently been found to be present in several tissues of brain and lung. Representative figures of the concentration of phospholipids in various tissues¹²⁰ and in isolated nuclei¹²¹ have been reported by several authors.

Cerebrosides

A method for the determination of cerebrosides has been developed by Brückner.¹²² It is based on the colorimetric determination of galactose by means of orcinol and sulfuric acid in the hydrolysate of the lipid extracts. So far as specificity is concerned, it is superior to the earlier reductometric methods¹²³; it should be mentioned, however, that Brückner's method cannot be applied to the determination of cerebrosides found in organs in Gaucher's disease.

Ottenstein, Schmidt and Thannhauser¹²⁴ have devised a method to determine galactosidocerebrosides and glycosidocerebrosides in organs that may contain both varieties of cerebrosides.

Cholesterol and Cholesterol Esters

Many methods of estimating total cholesterol and cholesterol esters have been published. The procedure of Schoenheimer and Sperry¹²⁵ requires more time than other methods but is the most reliable one for clinical use.

Total Lipid Fatty Acids

The total fatty acids in lipid mixtures are best determined by the method of Stoddard and Drury.¹²⁷

Neutral Fat

There is no reliable method for the direct estimation of neutral fat (glycerol fatty acid esters) in lipid mixtures that contain other fatty acid esters like phosphatides and cholesterol esters. One must therefore determine the total fatty acids in a lipid mixture and subtract from the value obtained the quantity of fatty acids contributed by both the total phospholipids and the cholesterol esters. The remainder, when multiplied by 104, represents

TABLE 4 Serum Analyses of Lipids in Various Diseases

CONDITION	TOTAL CHOLESTEROL mg/100 cc	CHOLESTEROL ESTERS % total cholesterol	CHOLESTEROL mg/100 cc	FAZE mg/100 cc	TOTAL PHOSPHOLIPIDS mg/100 cc	LECITHIN mg/100 cc	SPHINGO MYELIN mg/100 cc	TOTAL FATTY ACIDS mg/100 cc	NEUTRAL FAT mg/100 cc	REMARKS*
Normal values	150-260 350-800	70-75 Normal	40-70 100-250	40-70 100-250	150-250 250-430	100-200 220-400	10-30 Normal	200-450 500-900	0-150 Normal	Serum transparent, no increase in neutral fat, total fatty acids elevated because of high cholesterol esters and phospholipids, tuberos and plain skin xanthomas, tendon xanthomas and atberomas of blood vessels
Xanthomatousiliary cirrhosis	800-2200	Normal	240-640	240-640	800-2000	770-1950	30-50	1000-2500	0-60	Serum transparent, no increase in neutral fat, total fatty acids elevated because of high cholesterol esters and phospholipids, jaundice of years' duration in later stages total cholesterol decreases and ratio of cholesterol to cholesterol esters drops
Essential xanthomatosis, (conspicuous xanthoma- tous granuloma)	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Xanthoma disseminata of skin and cosmophilic xanthomatous granulomas of dura, brain, lung, osseous system, liver, spleen and lymph nodes occur singly, in various combinations or as a generalized form of the disease, no jaundice
Idiopathic (familial) hyper- lipemia, with hepato- splenomegaly and second- ary xanthomatosis	300-600	60-75	90-180	90-180	260-500	240-420	Normal	2000-4000	1000-3500	Serum creamy, occasionally eruptive secondary xanthomas, influenced by diet
Idiopathic hyperlipemia occasionally associated with slight diabetes	300-600	60-75	90-180	90-180	260-500	240-420	Normal	2000-4000	1000-3500	Serum creamy, severe degree of secondary eruptive xanthomas, influenced by diet
Hyperlipemia associated with severe diabetes and second- ary xanthomatosis	300-600	60-75	90-180	90-180	260-500	240-420	Normal	1500-3000	500-2000	Serum creamy, secondary eruptive xanthomas in- fluenced by insulin
Hyperlipemia in chronic pancreatitis, with second- ary xanthomatosis	300-600	60-75	90-180	90-180	260-500	240-420	Normal	1500-3000	500-2000	Serum creamy, rarely secondary xanthomatous, oc- casionally slight diabetes, other symptoms of pan- creatic disease present, influenced by diet
Hypercholesteremia asso- ciated with hypothyroidism	400-800	Normal	120-250	120-250	250-400	220-380	Normal	500-800	100-150	Serum transparent, rarely secondary xanthomatous, influenced by thyroid and diet
Localized foam-cell forma- tion (osteomyelitis, osteitis fibrosa cystica disseminata and xanthomatous mesenteric) Gaucher's disease	Normal	Normal	Normal	Normal	Normal	Normal	Normal	500-1000	150-400	Serum slightly milky, no secondary xanthomatous, low serum protein
	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Serum transparent
Nileman-Pick disease	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Reticulum cells and histiocytes of bone marrow, spleen, liver and lymph nodes contain large amounts of glycande cerobrosides, pigmentation in patches not present in all cases, infantile Gaucher's disease in generalized form and lesions are present in all organs
Tay-Sachs disease (amanotic idioey)	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Reticulum cells and histiocytes of all organs contain large amounts of sphingomyelin, cherry-red spot in macula of retina, observed in infants — rare in persons over two years
Hepatitis	260-400 300-400 Less than 100	40-60 30-40 10-30	100-260 210-280 70-80	100-260 210-280 70-80	Normal Low normal Lower than 100	Normal Normal Lower than 100	Normal Normal Low	Normal	Normal	No increase of sphingomyelin in organs, ganglions increased in brain cherry red spot in macula of retina
Acute	350-400	60-70	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Repeated estimations of the total cholesterol and of the ratio of cholesterol to cholesterol esters during the course of the hepatitis are helpful in the establishment of the prognosis of this disease
Chronic	400-500	40-50	200-300	200-300	Normal	Normal	Normal	Normal	Normal	In contrast to hepatitis, the cholesterol esters remain in the first stages of occlusion on the borderline of normal after a few weeks of occlusion the chole- sterol esters decrease, being a sign of hepato- cellular damage
Acute-yellow-atrophy type	260-400	40-50	130-240	130-240	150-400	110-370	Normal	Normal	150-500	
Complete obstruction of common bile duct by stone or tumor	350-400	60-70	Normal	Normal	Normal	Normal	Normal	Normal	Normal	
Acute	400-500	40-50	200-300	200-300	Normal	Normal	Normal	Normal	Normal	
Chronic	260-400	40-50	100-240	100-240	Normal	Normal	Normal	Normal	Normal	
Compensated portal cirrhosis	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal	
Alcoholic cirrhosis compli- cated by hepatitis and fatty liver	260-400	40-50	130-240	130-240	150-400	110-370	Normal	Normal	150-500	
Liver insufficiency of varied etiology	Less than 100	10-40	10-60	10-60	Low normal	Low normal	Normal	Normal	50-300	In conditions of liver insufficiency serum may be acidotic, but total fatty acids are normal but nutritive factors, being decreased

*Cerebrosides are not present in the serum in any of these diseased conditions

neutral fat.* The formula for the evaluation of neutral fat is as follows

$$[\text{Total fatty acids (mg. per 100 cc.)} - 0.72 \text{ cholesterol esters (mg. per 100 cc.)} + 0.69 \text{ total phospholipid (mg. per 100 cc.)}] \times 1.04 = \text{neutral fat (mg. per 100 cc.)}$$

The factors 0.72 and 0.69 assume an average fatty acid molecular weight of 277. Erroneously, the value obtained for total fatty acids is often taken as equal to the value of neutral fat. For these reasons the values of neutral fat reported in the literature are mostly too high. In cases in which the cholesterol present as esters and phospholipids is high in the serum, the error is great.

It can easily be seen that by a suitable combination of several of the procedures discussed above it is possible to achieve a rather complete quantitative partition of the phospholipids. It must be emphasized, however, that the accuracy of figures obtained by calculating a difference should be carefully examined in each case. Only in tissues are the total lecithin and total cephalin fractions so large that errors of the individual determinations do not seriously interfere with the calculation of the difference.

In the laboratory of the Joseph H. Pratt Diagnostic Hospital the following procedures are adopted in the routine determination of lipids in the serum for diagnostic purposes

For the determination of total cholesterol, free cholesterol and cholesterol present as esters the method of Schoenheimer and Sperry¹²⁴ is used. The only important change from the original method consists in the extraction of 1 cc. of serum in 25 cc. of acetone and alcohol (1:1).¹²⁵

The total phospholipids, the sum of lecithin and cephalin and the sphingomyelin are estimated by the procedure of Schmidt et al.¹¹⁸

The total fatty acids are determined by the method of Stoddard and Drury.¹²⁷

Neutral fat is evaluated from the figure obtained for total fatty acid minus the fatty acids present in cholesterol esters and phospholipids, according to the formula of Thannhauser and Reinstein.⁹ For the evaluation of neutral fat it is therefore necessary to determine the total fatty acids, cholesterol esters and total phospholipids.

The normal values of lipids in serum, expressed as milligrams per 100 cc., with these methods are as follows

Total cholesterol	150 to 260
Free cholesterol	40 to 70
Cholesterol esters	105 to 195*
Total phospholipids	150 to 250
Saponifiable phospholipids (lecithin and cephalin)	110 to 230
Sphingomyelin	10 to 30
Total fatty acids	200 to 450
Neutral fat	0 to 150
Cerebrosides	0

*Seventy to 75 per cent of total cholesterol.

Table 4 presents the results of serum analyses of lipids in various diseases

CASE 33411

PRESENTATION OF CASE

A seventy-year-old widow was admitted to the hospital because of "feeling very bad."

One week prior to admission the patient found herself unable to get out of bed one morning and complained of weakness and pain in the legs. She also noted occasional twinges of pain across the chest, lasting only a few minutes. These symptoms persisted until the time of admission and added to them was increasing shortness of breath. There was no severe pain, paroxysmal dyspnea or cough. There was said to have been some fever at the onset of the present illness, but no chills had been noted. The patient had always been in good health until four years before admission when she developed diabetes, which was controlled by diet and insulin. One year before admission she was seen in the Out Patient Department for scabies. A medical check-up at that time uncovered a history of some dyspnea and ankle edema, and on physical examination the blood pressure was 150 systolic, 90 diastolic. The heart was not enlarged, but a gallop rhythm was heard, there was slight pitting edema of the ankles and occasional rales at the lung bases. No digitalis was given, and the diabetes was controlled with a diet and 12 units of protamine-zinc insulin daily.

There was no history of hypertension, angina, intermittent claudication or orthopnea. The weight had remained stationary.

Physical examination revealed a pale woman lying flat in bed. There were many old retinal hemorrhages. The neck veins were distended and pulsating.

There were moist rales at both lung bases. The heart was enlarged, the area of dullness extending to the anterior axillary line, the rhythm was regular, with occasional extrasystoles, the sounds were somewhat distant, and to the left of the sternum in the fourth interspace was a rough, high-pitched sound, obscuring the first heart sound. This was believed to be a friction rub. The abdomen was protuberant but tympanitic in the flanks. The liver edge was felt one handbreadth below the costal margin and was firm and nontender. The spleen was enlarged to percussion. The ankle jerks and knee jerks were absent, and vibration sense was probably absent.

The temperature was 101.4°F, the pulse 90, and the respirations 28. The blood pressure was 130 systolic, 70 diastolic.

The urine gave a + test for albumin, a brown test for sugar and a + test for acetone, the sediment was normal. The hemoglobin was 10 gm per 100 cc., and the white-cell count 9500, with 85 per cent neutrophils. The serum protein was 7.26 gm per 100 cc., with an albumin-globulin ratio of 1.21, the van den Bergh reaction was 0.9 mg. per 100 cc. direct and 1.1 mg. indirect, and the cephalin flocculation test was + in twenty-four and +++ in forty-eight hours, the cholesterol was 181 mg., the cholesterol esters 100 mg., the nonprotein nitrogen 50 mg., and the fasting blood sugar 227 mg per 100 cc. The carbon dioxide was 25.4 milliequiv per liter.

An x-ray film of the chest showed a heart shadow greatly enlarged in all diameters. There was fluid in the pleural sinuses, and the lung roots and markings were prominent (Fig. 1). A film of the abdomen showed a large gallstone in the right upper quadrant and a shadow in the left upper quadrant compatible with an enlarged spleen.

An electrocardiogram showed sinus tachycardia, a rate of 120 and a PR interval of 0.12 second, with an elevated ST segment in Lead 1 and a depressed ST segment in Lead 3. The T waves were upright in Leads 1 and 2, flat in Lead 3 and upright in Leads CF₁, CF₂, and CF₃, the complexes in the limb leads were low.

The course continued to be febrile, the temperature swinging from 101 to 103°F. On the second hospital day the heart rate became regular again at a rate of 90. The friction rub disappeared. In spite of digitalis, quinidine, insulin and oxygen the patient did poorly. On the fourth hospital day the breathing became Cheyne-Stokes in character, the neck veins became more distended, and the chest was filled with moist rales. There was no tenderness or swelling of the legs. The white-cell count was 15,500, with 95 per cent neutrophils. The temperature rose to 103.5°F, the nonprotein nitrogen was 88 mg. and the fasting blood sugar 407 mg per 100 cc., and the carbon dioxide was 26.2 milliequiv per liter. On the fifth hospital day the temperature rose to 104°F, and the patient became unresponsive.

breathing rapidly. The heart sounds were distant and regular, the blood pressure was 110 systolic, 60 diastolic, and a paradoxical pulse was noted. Later during the same day the patient died.

DIFFERENTIAL DIAGNOSIS

DR CHARLES L. SHORT: May we see the x-ray films?

DR STANLEY M. WYMAN: This first film and the next film taken three days later show a grossly enlarged heart. Both films were taken with the patient in the supine position so that the exact size cannot be measured. There is no characteristic configuration. There is calcification in the region of the aorta, and in the lateral view the calcified area is seen descending in the chest. There is no gross dilatation of the pulmonary vessels. I cannot be sure of fluid in the pleural cavities, and it is impossible to exclude the possibility of fluid in the pericardial cavity. The patient has had an old fracture of the ribs, which I do not believe to be of any significance. The last film shows a gallstone, or an area of calcification described as being consistent with gallstone. It is difficult to see what is described as an enlarged spleen. I believe that the

FIGURE 1

spleen comes down to this point and is not definitely enlarged. I see no definite gas in the biliary radicles. There are no evident dilated loops of bowel.

DR SHORT: Is much pulmonary congestion apparent?

DR WYMAN: I should say that there is very little x-ray evidence.

DR SHORT: No more than what one might expect with a heart of that size?

DR WYMAN: The superior vena cava looks more prominent on the second film than on the first film, suggesting some degree of right ventricular failure.

DR SHORT: There is no question about one diagnosis in this patient—that is, the diabetes. This was at first mild and easily controlled with small doses of insulin, but at the time of admission it was resistant. At that time the patient had mild acidosis without appreciable lowering of the carbon dioxide. As a complication of diabetes she had evidence of retinopathy and probable peripheral neuritis, suggested by the weakness in the legs, the pain in the extremities and the absent reflexes. We must look beyond the diabetes, however, for the actual cause of death. It also seems clear that there had been some cardiac failure for at least a year and that at least some of the signs and symptoms of congestive heart failure had developed during the terminal illness. In addition, the fever and the leukocytosis suggest the presence of an infectious process at the time of and shortly before death. I think that we must first decide whether or not it is necessary to look outside the heart to explain the terminal illness. There was increasing nitrogen retention during the hospital stay. Were any further urine specimens available?

DR TRACY B. MALLORY: Three urine examinations were done, of which two revealed no cells in the sediment and the other disclosed only one or two white cells per high-power field. Albumin was present in all in small amounts.

DR SHORT: Certainly, from the urine examinations, we cannot decide that the patient had pyelonephritis. I am thinking especially of the type that is frequently found in diabetes: necrotizing renal papillitis. This diagnosis should be considered in any diabetic patient dying with evidence of urinary infection and progressive nitrogen retention. But, in the absence of pus in the urine, I do not believe that it is possible to make that diagnosis, and in any case it would not explain the findings in the chest.

The enlarged liver and the probably enlarged spleen, together with a very slight degree of jaundice, draw attention to the liver. There was also a slight depression of the serum albumin and a positive cephalin-flocculation test. It seems, however, that in the presence of both diabetes and heart disease more positive evidence is needed before liver disease can be regarded as either a primary or a secondary cause of death.

We are left to determine the type of cardiac disorder present—one accompanied by high fever and by a pericardial friction rub. Rheumatic carditis and pericarditis are possible at any age, although they seem unlikely in this patient, especially in the absence of any characteristic murmur. Acute isolated myocarditis, or Fiedler's myocarditis, is a rare cause of cardiac enlargement and failure, usually accompanied by fever. Since I should need more

extensive electrocardiographic changes to make that diagnosis, I shall mention it only in passing, along with another type of heart disease with fever — abscess in the myocardium. Coronary disease, which is common in both male and female patients with diabetes, must of course be considered. That may have accounted for the cardiac failure a year before admission and for the terminal illness in the form of an acute infarction. There are certain features against the diagnosis of coronary infarction in this patient, however. The pain in the chest was not characteristic. There was no marked fall in blood pressure. The electrocardiogram is not specific for recent infarction in view of the normal anterior-chest leads, although the slight changes may be accounted for by a previous infarction in another region of the heart. The height of the fever would be unusual in coronary infarction unless there were involvement of an extensive area of the heart. I therefore doubt that an acute coronary infarction was the cause of death. Of course, the height of the fever may be explained by a lesion elsewhere in the body, especially pulmonary infarction, but we have no evidence in its favor. A more appealing diagnosis to me is pericarditis of a purulent nature, which is a rash diagnosis to make in the absence of sepsis elsewhere or in the absence of pneumonia. As Dr Wyman has pointed out the x-ray studies are consistent with pericardial effusion. The friction rub is also consistent, as are probably the electrocardiographic changes. There are some atypical features about the patient that are helpful. When she came in she could lie down flat in bed, and as Dr Wyman pointed out, there is very little x-ray evidence of congestive failure. This diagnosis would explain the high fever and, I believe, the other aspects of the case, except for the nitrogen retention, and I should therefore like to present it with some hesitation as the diagnosis.

DR ALFRED KRANES: Would Dr Short care to comment on the possibility of acute bacterial endocarditis? Having just missed a case at one of these conferences I bring it up for his consideration.

DR SHORT: We have a patient who died with fever. We have no other positive evidence, have we?

DR KRANES: No, except that attention is drawn toward the heart, and there was a questionably enlarged spleen. I do not see how one can establish the diagnosis, but perhaps one should consider it as a possibility.

DR SHORT: Yes, I should have mentioned it as a possibility. I agree that there is not enough evidence to make the diagnosis, however.

DR CONGER WILLIAMS: It should be emphasized that those who took care of this patient were limited to the objective findings. The history was entirely worthless because of language difficulty. We thought at first that the history did not suggest myocardial infarction. Later, on learning the electrocardiographic findings, we inclined more

toward that diagnosis. We did consider pericarditis but thought that myocardial infarction was more probable.

CLINICAL DIAGNOSES

Myocardial infarction
Congestive heart failure
Diabetes mellitus

DR SHORT'S DIAGNOSES

Purulent pericarditis
Coronary heart disease

ANATOMICAL DIAGNOSES

Abscesses, myocardial, left ventricle
Pericarditis, fibrinopurulent, acute
(Diabetes mellitus)
Hydrothorax, bilateral, moderate
Pulmonary atelectasis, lower lobes, bilateral
Cirrhosis of liver
Rheumatic heart disease
Endocarditis, chronic, rheumatic, mitral valve, slight
Arteriosclerosis, generalized, severe, with ulcerations in aorta
Intercapillary glomerulosclerosis

PATHOLOGICAL DISCUSSION

DR MALLORY: Autopsy showed a serofibrinous pericarditis and a greatly hypertrophied heart. On cutting into the heart we found a large abscess of the myocardium, and microscopically many smaller abscesses were observed throughout the myocardium. I think that the pericarditis was unquestionably secondary to the myocardial abscesses. The coronary arteries were markedly sclerotic, but none were occluded. The lungs showed only severe passive congestion — no pneumonia or infarction. Nowhere in the body did we find any other septic focus, there were no other abscesses to which this myocardial abscess might have been secondary.

There was a severe degree of cirrhosis of the liver of a rather nonspecific type that I could not classify. The organ was quite granular grossly, distinctly tougher than normal, and fat infiltration was present in some areas and absent in others. The spleen was hypertrophied, weighing 500 gm, and was fibrotic, indicating that there had been some significant degree of portal hypertension. The kidneys were slightly large, weighing 400 gm, and showed early changes of the type described by Kimmelstiel and Wilson¹ — intercapillary glomerulosclerosis. I doubt if the process had become sufficiently extensive to have had much to do with the symptomatology.

DR ALLAN M. BUTLER: What did the culture show?

DR MALLORY: A culture of the pericardium showed *Staphylococcus aureus*. In a survey of ab-

accases of the myocardium in about 30 cases, reported by Weiss and Wilkins² some years ago, 80 per cent were due to the staphylococcus and the remainder to a scattering of other organisms.

DR BUTLER The post-mortem blood culture showed no growth?

DR MALLORY Cocci were present, and other organisms as well, there was undoubtedly a contamination.

DR SHORT Was there actual rupture into the pericardium, or was it involved merely by extension?

DR MALLORY Merely by extension.

A PHYSICIAN Did the marked arteriosclerosis of the aorta have anything to do with it?

DR MALLORY There was marked sclerosis present. I cannot see any way in which it could have contributed to the symptoms.

CASE 33412

PRESENTATION OF CASE

A fifty-two-year-old unmarried typist was referred to the Out Patient Department because of persistent cough and nervousness.

She had apparently been in good health until four and a half months before entry, when she noticed swelling and a dull pain in the legs, slight shortness of breath and a mild, persistent cough productive of white, mucoid sputum. She was then admitted to another hospital, where examination revealed hypertension, an enlarged heart, slight dependent edema and enlarged hilar lymph nodes on x-ray study. She was treated with digitalis, Schemm diet, iron and chest radiation, consisting of four doses of 200 r each. The symptoms cleared, but after six weeks there was still no change in the hilar lymph nodes. The patient was then told that she had Hodgkin's disease, whereupon she became disturbed and despondent. Two weeks before entry she noticed lumps on the right side of the neck. By that time she had lost considerable weight — from 160 pounds a year previously and 150 pounds four months previously to 132 pounds on admission.

The patient had had tuberculous cervical adenitis many years previously, and a hysterectomy had been performed for fibroids seven years before admission. Since then she had been subject to menopausal flashes.

Physical examination revealed a thin, nervous and anxious woman. The fundi showed only slight arteriovenous compression. In the neck there was scarring and induration under the right mandible. There were three hard supraclavicular nodules, 0.5 cm in diameter, on the right and smaller, soft, palpable, anterior cervical lymph nodes. The lungs

were normal. The heart was slightly enlarged, the border of cardiac dullness extending to the left. There was slight pitting edema, especially of the left ankle, associated with many telangiectases. Abdominal, pelvic and neurologic examinations were negative.

The temperature was 99°F, the pulse 80, and the respirations 20. The blood pressure was 215 systolic, 115 diastolic.

Examination of the blood disclosed a red-cell count of 4,380,000, with a hemoglobin of 13.8 gm, and a white-cell count of 8200, with 55 per cent neutrophils, 2 per cent large lymphocytes, 25 per cent small lymphocytes, 12 per cent monocytes, 4 per cent eosinophils and 2 per cent basophils. The total serum protein was 6.90 gm per 100 cc, with 4.7 gm of albumin and 2.2 gm of globulin (albumin-globulin ratio of 2.1). The urine was normal. A guaiac test of the stool was negative, as was a blood Hinton test.

An x-ray film of the chest (Fig. 1) showed thickened lung roots and swelling of the right paratracheal lymph nodes. The lung markings were increased, and the left leaf of the diaphragm was obscured. The spleen was not enlarged.

A biopsy of a cervical lymph node was done.

DIFFERENTIAL DIAGNOSIS

DR WILLIAM MCK JEFFRIES May we see the x-ray films?

DR STANLEY M WYMAN These films show rather symmetrical enlargement of the lymph nodes at both hili, and there is apparently one large node in the right paratracheal region. The vascular shadows in both lung fields are diffusely prominent, and in the left lower-lung field there is some mottled infiltration, partially obscuring the diaphragm and apparently lying in the lower lobe. The heart shadow is slightly increased in size, enlargement being chiefly toward the left, possibly owing to left ventricular enlargement.

DR JEFFRIES The chief problem presented in this case is one of the differential diagnosis of the causes of enlargement of the mediastinal lymph nodes in a woman of fifty-two years. There are very few positive findings in the history, physical examination or laboratory studies that give a clue to the nature of the process.

The patient had noticed no symptoms until four and a half months before entry, at which time dyspnea, leg edema and a persistent productive cough developed. At another hospital she was found to have hypertension and an enlarged heart, as well as enlarged hilar lymph nodes, and after treatment with digitalis, iron and 800 r of x-ray therapy, the symptoms cleared without evident change in the size of the nodes, suggesting that the edema and dyspnea were due to hypertensive heart disease with failure. The cough apparently recurred, however, since we are told that it was a presenting com-

plaint at the time of admission to this hospital. When the lymph nodes failed to respond to x-ray treatment, the patient was told that she had Hodgkin's disease, but apparently no biopsy was taken — probably because no suspicious superficial lymph nodes had presented themselves at that time. Two weeks before entry here, however, lumps appeared in the right supraclavicular area. In the meantime she had lost 28 pounds during the previous year, 18 of which had been lost in the four months prior to entry. Some of this weight loss may have resulted from digitalization. We are not given any information regarding her appetite, but we are told that she

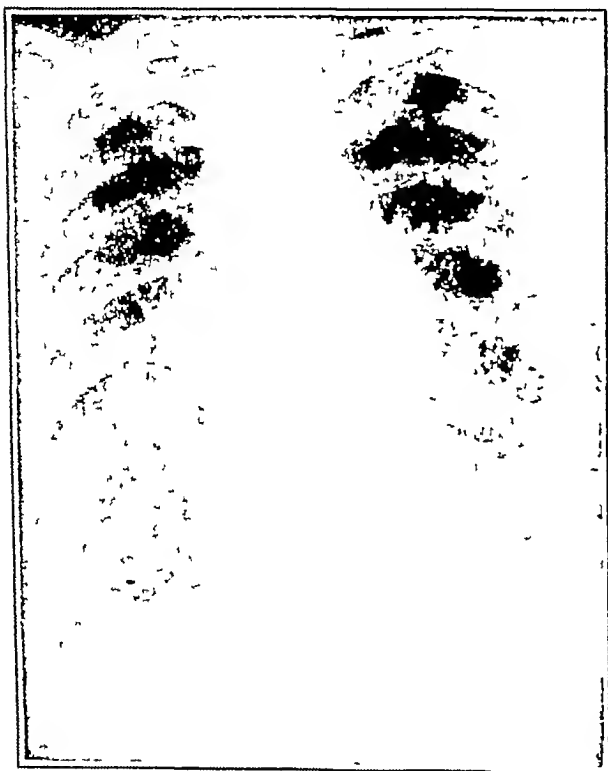

FIGURE 1

had become disturbed and despondent after hearing that she had Hodgkin's disease, so that a good part of the weight loss may have been due to emotional disturbance rather than to the underlying disease.

We are therefore obliged to explain the cause of the enlargement of the mediastinal, right supraclavicular and anterior cervical lymph nodes, associated with productive cough of four and a half months' duration and weight loss, which may or may not have been related.

Could this patient have had Hodgkin's disease? That is certainly one of the most frequent causes of enlargement of mediastinal and cervical lymph nodes. It can occur at any age. Although it is somewhat more frequent in males, 30 to 40 per cent of reported cases have been in females. The descrip-

tion of the supraclavicular and cervical lymph nodes is compatible, since Hodgkin's nodes are usually rather discrete and may vary greatly in texture. The blood studies are not particularly helpful. This patient had comparatively normal red-cell and white cell counts, with a slight increase of monocytes on the differential smear. Although patients with Hodgkin's disease most frequently show a normochromic or hypochromic anemia, with a moderate leukocytosis and an increase in the polymorphonuclear neutrophils, normal counts are not unusual. The eosinophil count of 4 per cent is at the upper limits of normal, but it is now realized that eosinophilia is not so common in Hodgkin's disease as it was formerly thought to be.

The history of failure of the mediastinal lymph nodes to respond to x-ray treatment is somewhat against Hodgkin's disease, although some radiologists report that a dosage of over 1000 r is necessary to cause decrease in size of some mediastinal lesions of this disease. The remarkably symmetrical enlargement of the hilar lymph nodes is also apparently unusual in Hodgkin's disease, so that it might be worth while to consider other possibilities in this case.

Other types of lymphoma should be considered, but here also the lack of radiosensitivity makes this diagnosis rather unlikely.

Could this have been tuberculosis? The history of tuberculous cervical adenitis many years previously is suggestive, but the paucity of clinical signs and the appearance of the mediastinal nodes on x-ray examination are unusual for this disease. Tuberculous mediastinal lymph nodes would not ordinarily be so large or so symmetrically distributed as those in this case.

Bronchiogenic carcinoma can likewise probably be dismissed on the basis of the x-ray picture of symmetrically enlarged hilar lymph nodes.

There is a condition, however, in which such symmetrical enlargement of the hilar nodes, accompanied by enlargement of the paratracheal nodes, and varying degrees of peripheral lymphadenopathy are described as characteristic — that is, Boeck's sarcoidosis.¹ It seems to occur most frequently in younger persons, the greatest incidence being in the third decade, but cases have been reported in patients up to seventy-four years old. The sex incidence is fairly equally distributed between males and females. A characteristic x-ray finding in addition to the striking enlargement of the mediastinal lymph nodes is pulmonary infiltration with linear or nodular densities.² There are few or no clinical symptoms, although the occurrence of cough has been reported in a few cases. It is remarkable that even in the presence of greatly enlarged hilar and paratracheal lymph nodes, there is usually no evidence of compression of the trachea or bronchial tree. So far as I know these nodes are not radiosensitive. The blood picture is not characteristic

but the white-cell count is usually normal or low, and an increase in monocytes, with an otherwise normal differential, has been noted in some cases. An eosinophil count of up to 35 per cent has been reported in about a third of the cases. A striking feature found in many cases of sarcoidosis but not observed in this case is an elevation of the plasma globulin, the albumin and globulin were within normal range in the case under discussion. Characteristic areas of cyst-like rarefaction in the bones of the hands and feet have also been reported in approximately 10 per cent of cases in this country, but no mention is made of x-ray studies of the hands or feet in this case.

DR WYMAN: X-ray films of the hands and feet were taken but showed no abnormality.

DR JEFFRIES: That indicates that sarcoidosis was also suspected. Uveoparotid fever has also been reported in over a third of cases of this disease but was not present in this case.

The weight loss is unusual for sarcoidosis, but some loss of weight has been reported in a few cases and as I have already mentioned, this patient may have lost weight because of emotional disturbance or digitalization.

Finally, two other conditions that may cause chest x-ray findings of this nature should be mentioned. Coccidioidomycosis, or San Joaquin Valley fever is one, but the clinical course is similar to that of influenza or primary atypical pneumonia, chest pain being a prominent feature, and the white-cell count is usually elevated. Patients with this condition usually give a history of having visited or lived in the endemic areas of southwestern United States. The other is erythema nodosum, but in the absence of the classic skin lesions of this condition one could hardly make the diagnosis. It has been suggested by some that erythema nodosum is related to sarcoidosis, and erythema nodosum has also been reported in cases of coccidioidomycosis, so that

the similarity of mediastinal x-ray findings may be more than coincidental.³

Therefore, we are left with two chief possibilities: Hodgkin's disease and sarcoidosis, and on the basis of the clinical picture, the x-ray findings and the resistance to x-ray treatment, sarcoidosis seems to have been slightly more probable.

CLINICAL DIAGNOSIS

Sarcoidosis?

Hodgkin's disease?

DR JEFFRIES'S DIAGNOSIS

Sarcoidosis

ANATOMICAL DIAGNOSIS

Sarcoidosis

PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN: Biopsy of the cervical lymph node showed the characteristic microscopical findings of sarcoidosis. The node was almost completely replaced by well formed groups of epithelioid cells in good tubercle formation. Langhans giant cells were present in moderate numbers. In a few places there were small areas of necrosis, but this finding does not mean tuberculosis. We have seen foci of necrosis in well established cases of sarcoidosis. It would be interesting to have had a tuberculin test, in the majority of cases with sarcoidosis, the tuberculin test is negative.

A PHYSICIAN: When the patient was seen in the Out Patient Department three months after the biopsy, no change was noted in her condition.

GREATER BOSTON COMMUNITY FUND

PHYSICIANS are well aware of the need for the different kinds of service that more than three hundred Red Feather agencies of the Greater Boston Community Fund give to the people of this close-knit area of fifty cities and towns. Undoubtedly, they are familiar with the medical services offered, in which most of them probably take an active part. The medical profession is so close to the medical aspects, however, that the other valuable services to the community that the Red Feather symbolizes may be overlooked.

Of each dollar contributed last year, youth agencies and neighborhood houses received the largest share — 30 cents — for wholesome recreation for 290,562 people of all ages. Hospitals and dispen-

saries, which received 28 cents of the dollar, provided free or partly free care and 719,897 examinations and treatments for 28,435 patients. Next in line were family services, which received 19 cents of the dollar and which helped 20,773 families in time of trouble. Child-caring agencies — allotted 10 cents of the Red Feather dollar — gave 347,180 days of motherly care in foster homes to neglected children and 35,956 days to small children in day nurseries and nursery schools. Of the remainder of the dollar, 5 cents went to visiting-nurse care, 4 cents for the handicapped and aged, and 4 cents for fifty-four diversified special services.

Physicians affiliated with Red Feather hospitals may regard some of the services that they contribute as fulfilling the demands that the community makes on them. Money, however, is also needed to help meet operational expenses of all the Red Feather agencies, struggling against mounting costs in every field. It is well to remember that, whereas two out of five families in Greater Boston receive direct help from Red Feather services, everyone benefits in some way from the protection that these health and social agencies give to the community.

In the aftermath of war, the needs have increased — the old ones have been accentuated, and many new ones have developed. Family life has been disrupted and broken. Health and nerves have been taxed to the danger point. There is confusion and relaxation of normal standards. Young people are restless and undisciplined. Family and child welfare agencies probably bear the brunt of these increased needs as they face the situations caused by breaking of homes during the war, the soaring figures on illegitimacy, the unhappy young couples who married too hastily and the tremendous upsurge of juvenile delinquency.

Remembering that there are many needs beyond the call of medical duty, physicians should do their utmost to enable the Red Feather services to carry on in 1948.

SULFADIAZINE-RESISTANT STREPTOCOCCAL INFECTIONS AMONG CIVILIANS

AT THE height of the war, certain personnel of the armed services participated in a program of continuous prophylaxis with daily small doses of sulfa-

diazine in an attempt to minimize the number of man-days lost through streptococcal illness, particularly during the crucial initial training period. Among the possible complications that were expected to arise out of this program were the development and spread of sulfonamide-resistant strains of bacteria. The occurrence of such resistant organisms in military units was subsequently reported, and because of this the chemoprophylactic program was abandoned.

The mode of development of the resistant strains of bacteria has not been settled. It has been shown that strains of streptococci with slight degrees of sulfadiazine resistance appeared among Army personnel about the time when the program of mass chemoprophylaxis had already been in progress in the Navy for several months. It is possible that these slightly resistant strains were the precursors of the more highly resistant ones that later became established. It is also possible that resistant strains were transferred from certain Navy personnel who had been subjected to the prophylactic program and might have become carriers of the highly resistant streptococci. Interestingly enough there was no evidence of the existence of sulfonamide-resistant strains of hemolytic streptococci prior to the institution of the mass chemoprophylactic program.

The evidence to date seems to indicate that all strains of hemolytic streptococci that were present in the civilian population prior to the time of mass chemoprophylaxis in the armed forces were susceptible to the action of sulfonamides. Furthermore, there is some evidence to show that the therapeutic doses of sulfonamides, as usually prescribed among civilians, do not cause the development of resistant organisms.

Since large numbers of personnel in the armed services were exposed to sulfonamide-resistant strains and since there were many opportunities for mingling of service personnel with civilians, it could be anticipated that sooner or later the resistant streptococci would be found among civilians. The occurrence of an outbreak of streptococcal infections due to a resistant strain has now been reported among civilians in a small community by Johnson and Hartman*.

Early in 1946 an epidemic of scarlet fever occurred in Cooperstown, New York. The first 8 patients that were studied were found to harbor Type 19 hemolytic streptococci. This was one of the types that had been found to account for a large proportion of the sulfonamide-resistant streptococci that spread among military personnel. It was decided, therefore, to determine whether the strains from this outbreak were sulfonamide-resistant. All eight strains were found to be resistant to sodium sulfadiazine in a concentration of 25 mg per 100 cc.

This offered a unique opportunity to study the incidence of sulfonamide-resistant hemolytic streptococci in a small community. Cultures were obtained from patients living in Cooperstown and in the surrounding area of Otsego County who were suspected of having streptococcal infections. Strains from 100 patients were collected between the middle of February and the end of April, 1946. Two specific types were found to predominate: Type 3, which accounted for twenty-eight strains, and Type 19, which accounted for twenty-four strains. The remaining strains were of other specific types or could not be typed with the available diagnostic serums. All but one of the Type 19 strains were found to be sulfadiazine-resistant, whereas none of the remaining strains were resistant.

Of the cases of drug-resistant infection, 14 were clinical scarlet fever, and 9 were simple pharyngitis; 9 cases occurred in adults, and the rest were in children of school age or younger. The first case of scarlet fever occurred in a boy who was attending public school, following the onset of his illness, several of his classmates developed scarlet fever, and Type 19 sulfadiazine-resistant streptococci were isolated from all. The same organism was isolated from the parents, siblings and contacts of children originally infected in this public school. There were 3 patients, however, who had had no contact with any of these patients, nor had they had any known contact with recently discharged or active members of the armed services.

It is stated that these cases offered no particular therapeutic difficulties. It is not mentioned, however, whether any specific antibacterial agent, particularly sulfadiazine, was used. Obviously, if these cases were mild and if penicillin were used, as would be expected

*Johnson R. D., and Hartman T. L. Sulfadiazine resistant streptococcal infections in civilian community. *J. Clin. Investigation* 26:325, 328, 1947.

The development of resistance to antibacterial agents has become particularly important since the introduction of streptomycin. The emergence of streptomycin-resistant strains during treatment has been one of the most important factors limiting the successful use of that antibiotic. Drug-fastness, moreover, is the most important factor limiting the usefulness of the sulfonamides in the treatment of gonococcal infections. Fortunately, penicillin has been highly effective against infections with sulfonamide-resistant strains of gonococci. Furthermore, the widespread use of penicillin has thus far failed to give rise to penicillin-resistant strains to any significant extent. Whether attempts to use penicillin prophylactically on a wide scale or over a long period would result in the emergence of penicillin-resistant strains remains problematic.

In the meantime it is important to be on the lookout for the appearance and spread of pathogenic bacteria resistant to the chemotherapeutic and antibiotic agents, particularly in patients in whom the results of therapy with such agents are disappointing.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

BROWN — Martin M. Brown, M.D., of North Adams, died on September 18. He was in his eighty-fifth year.

Dr. Brown received his degree from Rush Medical College in 1888. He had practiced medicine and surgery in North Adams for fifty-six years. He was a fellow of the American College of Surgeons and the American Medical Association.

CHARRON — Ovide Toussaint Charron, M.D., of New Bedford, died on May 26. He was in his sixty-fifth year.

Dr. Charron received his degree from College of Physicians and Surgeons, Boston, in 1912. He was a former member of the Massachusetts Medical Society.

COWLES — Frank Augustus Cowles, M.D., of Beverly, died on May 21. He was in his eighty-eighth year.

Dr. Cowles received his degree from University of the City of New York Medical Department in 1881. He was a former member of the Massachusetts Medical Society.

HIGGINS — George V. Higgins, M.D., of Randolph, died on September 8. He was in his sixty-seventh year.

Dr. Higgins received his degree from Tufts College Medical School in 1906. He was a former president of the Norfolk South District Medical Society and for thirty-five years was associate medical examiner for Norfolk County. He was a fellow of the American Medical Association.

His widow and three brothers survive.

JOHNSON — Mary W. L. Johnson, M.D., of Boston, died on September 15. She was in her eighty-first year.

Dr. Johnson received her degree from Women's Medical College of Pennsylvania in 1894. From 1905 to 1912 she was assistant superintendent of Inwood Sanitarium, Conshohocken, Pennsylvania, and in 1914 she founded Bellevue Hospital in Chestnut Hill.

A daughter and two nephews survive.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

DIAGNOSIS OF UNDULANT FEVER BY LABORATORY TESTS

It is exceedingly difficult to make a diagnosis of undulant fever solely on the basis of clinical data. Among the diseases to be differentiated from it are infectious mononucleosis, tuberculosis, typhoid and similar enteric fevers, syphilis, malaria, subacute bacterial endocarditis, tularemia, Hodgkin's disease and rheumatic fever. In both the acute and the chronic phases of the disease, confirmation of the diagnosis rests on the relative evaluation of several specific laboratory tests: primary isolation of the Brucella organism by cultural methods from the blood, other body fluids or tissues of the patient, indirect recovery of Brucella by culture after animal inoculation, the agglutination reaction, and the intradermal and the opsonocytaphagic tests. The first two procedures are self-explanatory and will not be discussed.

The *agglutination test* is most valuable diagnostically in acute cases. Agglutinins may appear as early as the fifth day but ordinarily do not until ten to fourteen days after the onset of the disease. Agglutination of Brucella antigen to titers of 1:135 is usually considered significant and presumptive evidence of an active infection with typical clinical symptoms. In some cases, particularly of the chronic type, agglutinins cannot be detected throughout the course of the disease. Furthermore, a significant agglutinin titer may not always indicate that the presenting symptoms result from active brucellosis. Agglutinins are present in the blood for many years after an infection. A positive agglutination merely indicates that the organism has successfully invaded the host ten days or more prior to the performance of the test. Furthermore, patients with tularemia may show agglutinins in low titer for Brucella, as may those treated with cholera vaccine (this may be confusing among former servicemen who received cholera prophylaxis) or infected with *Vibrio comma* (*V. cholerae asiaticae*). It has been reported that the serum of 3 to 9 per cent of patients with tuberculosis will give a false-positive reaction to this test; another study, however, has shown that a moderate number of patients with tuberculosis have had undulant fever at some time. Occasionally, cross-agglutination may occur in the presence of infection with *Eberthella typhosa*, *Proteus vulgaris* (X19 strain) and, more rarely, in other infections.

The *intradermal test* is an allergy test detecting sensitization to Brucella. An appropriate Brucella antigen (0.1 cc of "Brucellergen," or 0.02 cc of 1:10 dilution in physiologic saline solution of a bacterial suspension of 4,000,000,000) is injected into the skin of the flexor surface of the forearm. In positive cases, the reaction begins in twenty-four hours, rapidly spreading from 2 to 10 cm in diameter, with erythema, considerable circumscribed edema and pain or itching, all of which may last up to nine days. The local reaction may be accompanied by an exacerbation of symptoms in infected patients and a mild systemic reaction in those hypersensitive to Brucella. A nonspecific reaction may appear within the first twenty-four hours, consisting of an area of erythema 1 to 2 cm in diameter, which is of no significance and is rarely seen at the end of forty-eight hours. A positive cutaneous reaction signifies a past or present infection with Brucella.

It must be strongly stressed that whenever a skin test is to be performed, a blood sample for an agglutination test should be taken *before* the skin test. A false-positive agglutination test in low titer may result when the latter procedure is done after the skin test. This may be due to a previous exposure to the skin-test antigen. Secondly, a skin-test dose of antigen may act as a booster dose, elevating the Brucella agglutinin titer in the serums of previously infected patients to a significant level (even though the titer is not contributing to the pre-

senting illness) Therefore, the intradermal test should be deferred until all information obtainable from the agglutination test has been secured

The *opsonocytophagic test* as developed by Huddleson should be performed within seven days of the onset of the illness. In this procedure equal volumes of the patient's citrated blood and a saline suspension of living *Brucella* are mixed. After thirty minutes of incubation, a smear is made from the centrifuged mixture. The number of bacteria in 25 polymorphonuclear leukocytes is counted. If no cells are found in the leukocytes, the test is negative, if the number is less than 20, the opsonocytophagic power is considered to be slight, if between 20 and 40, it is moderate, and if over 40, it is marked. A positive skin-test reactor is considered infected if less than 50 per cent of cells show marked phagocytosis, questionably infected or immune if 50 to 80 per cent of cells show marked phagocytosis and immune if 80 per cent or more reveal marked phagocytosis. A negative skin test and little or no phagocytic activity indicate susceptibility to infection. It has been noted that patients infected with *Brucella melitensis* frequently show phagocytosis as high as immune subjects, therefore, a high opsonic activity does not always indicate immunity.

Other laboratory procedures have been employed in diagnosis, — namely, the precipitin and complement-fixation tests and various therapeutic tests, — but they have proved to be too inconclusive for wide general use.

No single test considered individually, with the exception of positive culture from the patient or through animal inoculation, is conclusive. All should be evaluated from a relative standpoint, and the results weighed carefully with the history and the clinical picture before a definite diagnosis is made.

Appropriate tests can be used to rule out the confusing diseases mentioned above. Agglutination tests for typhoid and paratyphoid B are routinely performed by the State Diagnostic Laboratory on all blood samples sent in for undulant-fever agglutination. On request, a heterophil-antibody titration for the diagnosis of infectious mononucleosis is done on the same blood.

CORRESPONDENCE

EFFECT OF LARGE DOSES OF IRRADIATION ON GASTRIC ACIDITY

To the Editor: The article by Dr Irving B. Brick entitled "The Effect of Large Doses of Irradiation on Gastric Acidity," which appeared in the July 10 issue of the *Journal*, has been read with great interest. However, it seems to me to contain certain fallacies to which attention should be drawn.

In the first place the title and the article itself imply, and, indeed, state that the effect of large doses of irradiation on gastric acidity have been studied. In fact, the "radiation was delivered to the antrum of the stomach rather than to the upper part." It is a well recognized fact that the antrum does not secrete acid juice, the cells secreting acid and pepsin are located in the middle and upper portions of the

stomach. Dr. Brick seems to take cognizance of this fact but considers it only a "possible explanation." He specifically states that in previous studies using the 10 by 10 cm. portals described "it was shown that the effects both radiographically and pathologically are confined mainly to the antral and pyloric regions" (italics mine). How then can he draw any conclusion regarding the effect of irradiation on gastric secretion when he has not irradiated the acid-secreting portions of the stomach?

Furthermore, I must protest against the sweeping statement in the summary that "the use of radiation has no place in the treatment of peptic ulcer, since it has been shown that deleterious effects on the stomach can be obtained with this agent." Surely the author would not contend that all agents with which "deleterious effects can be obtained" should be removed from our therapeutic armamentarium!

The demonstration by Dr. Brick of antral ulcers in 9 patients after intensive radiation of that region for tumor is important, but it is not pertinent to the problem of peptic ulcer. The lesions seem clearly due to radiation necrosis and are not analogous to spontaneous peptic ulcers. The susceptibility of the gastric and intestinal mucosae, and, indeed, of all living tissue, to irradiation, given in adequate dosage, is well recognized. The fact that radiation may produce tissue necrosis under certain circumstances does not prove radiation to be of no value under other circumstances. Specifically if radiation were able to destroy the acid-secreting cells of the gastric mucosa the procedure might be of very great value in the treatment of peptic ulcer, a disease, by the way, not entirely of "unknown etiology."

I regret the necessity of finding fault with an excellent study. As Professor A. J. Carlson has often said in effect "Facts are never in error regardless of how wrong the interpretation may be." I am sorry that Dr. Brick did not restrict his discussion to the evidence presented.

WAITER L. PALMER, M.D.

Department of Medicine
University of Chicago

* * *

Dr. Palmer's letter was referred to Dr. Brick, whose reply is as follows:

To the Editor: I wish to thank Dr. Palmer for the interest displayed and the astute criticism of some of the conclusions.

As pointed out in my article, these studies on gastric acidity were made on patients with normal stomachs. The effect of radiation, which was being given for malignant disease extrinsic to the stomach, on gastric acidity was of some interest in determining whether or not the course of radiation injury of the stomach was altered by the degree of gastric acidity. There did not appear to be any correlation of the course and degree of gastric acidity. While, with the technique of irradiation used in these cases, the major portion of the radiation is directed at the antral portion of the stomach, there is undoubtedly overlap of radiation effect of the upper portion of the stomach as demonstrated at operation (Bowers, R. F., and Brick, I. B., *Surgery* 22:20, 1947). The most drastic injury appeared in the antrum and pylorus, but there appeared evidence of radiation effect throughout the stomach in the form of edematous thickening and avascularity. Submucosal edema and cellular changes of a nonspecific nature were noted histologically in sections from the fundus.

More relevant to the discussion is the careful study of Drs. W. L. Palmer and F. Templeton (*J. A. M. A.* 112:1429, 1939) in which dosages of 1100 to 3600 r were directed to the upper portion of the stomach in patients with peptic ulcer. The charts accompanying the article reveal the extreme variability of reaction of gastric acidity to the radiation. One patient receiving 3600 r had a minimum depression of gastric acidity while another receiving only 1097 r had a rather prolonged depression (more than one hundred and sixty days). It is this extreme variability, which we also have encountered not only in the effect on gastric acidity but also in the radiation injury to the stomach, that deserves emphasis. Why some patients can receive 5000 to 6000 r and reveal no evidence of injury to the stomach and another patient receiving a dosage as low as 2424 r with the same technique (as in Case 9 in my article) will develop an ulcer, is a question of individual tissue tolerance to radiation worthy of further study. With the dosages used by Dr. Palmer, in 1 case receiving 2965 r hepatic necrosis was observed at operation and only a moderate depression of gastric acidity was ob-

ained. In another patient who received 3227 r study of the gastric mucosa was possible since the patient died of an entirely unrelated coronary occlusion one day after completion of radiation therapy. The pathologist reported that the mucosa revealed profound alterations everywhere especially in the fundus. This, too, affords some evidence that there is apparent overlap of the radiation effect since in these cases the radiation was directed only to the upper part of the stomach. Drs. Palmer and Templeton made no claim whatever for the efficacy of radiation in the treatment of peptic ulcer nor did they advocate its use or delineate any place that such treatment might have in peptic ulcer. I have not been able to find in the literature the results of the continuation of this interesting study or any other using the same range of dosage of radiation.

It is from this study of Dr. Palmer and from my own that the conclusion that radiation has no place in the treatment of peptic ulcer was drawn. That conclusion should have been qualified by the addition of 'with the dosages of radiation studied.' For with the dosages used both in the cases of Drs. Palmer and Templeton and in my cases the effect on gastric acidity was extremely variable, being unpredictable in the individual case, and the possibility of radiation injury was present. Furthermore we are sure that over a longer period of observation there might not be progressive changes due to radiation? The well known progression and complications of x-ray skin burns may be an instance in analogy.

I can only agree with Dr. Palmer that if radiation were able to destroy the acid-secreting cells of the gastric mucosa the procedure might be of great value in the treatment of peptic ulcer but hasten to add that the dosage must be a safe one free of potentially serious dangers in the treatment of a disease in which the group with which Dr. Palmer is associated has had notable success by means of methods other than radiation. I believe that with the present knowledge of radiation effect on the stomach with and without peptic ulcer the use of radiation in the treatment of peptic ulcer should be limited to investigative personnel doing carefully controlled clinical research as illustrated notably by Dr. Palmer and associates. To date no one has claimed to be able to produce destruction of the acid-secreting cells of the gastric mucosa with radiation regardless of dosage.

In closing I should like to call attention to a paper not available to me at the time of publication of my article in the *Journal*. Drs. Palmer, Levin and Hamann (*Gastroenterology* 8:565 1947) using dosages of radiation varying from 1350 to 1710 r over the body and fundus of the stomach studied the effect on nocturnal gastric secretion in patients with duodenal ulcer. No toxic effects were noted. The variability of depression of gastric secretion in the period studied (fourteen to one hundred and fifty days) is again pointed out. Since the patients had received antacid therapy prior to radiation this is not a strictly controlled study. No claim is made for the use of radiation in the treatment of peptic ulcer.

It is hoped that cases studied over a longer period will be available to determine the effect of safe radiation dosages on the chronic recurring disease that is peptic ulcer. Such a study may properly lead to a more adequate evaluation of the place that radiation holds in the therapy of peptic ulcer than I have been able to conclude from the available data.

BOOK REVIEWS

Penicillin in Neurology By A. Earl Walker, M.D. and Herbert C. Johnson, M.D. 8 cloth 202 pp. with 72 illustrations. Springfield, Illinois: Charles C. Thomas, 1946 \$5.00.

When penicillin was discovered as a therapeutic agent it was at once suggested as having probable value in diseases of the nervous system particularly those due to infections. Although relatively nontoxic when given parenterally the drug was not so innocuous when applied directly to the nervous system. If injected subcutaneously it did not reach the cerebrospinal fluid. Thus, for the treatment of meningitis and some other infections the drug had to be put directly into the intrathecal space. An effort was made, moreover, to apply it directly to the nervous system particularly the brain when

exposed by surgical means. The authors, who at the time this book was compiled were in the United States Army had wide experience in the use of penicillin. Dr. Walker was at the Cushing General Hospital and Dr. Johnson served at the Lawson General Hospital.

Penicillin is somewhat toxic when given intrathecally or placed directly on the cerebral cortex. In this monograph the reactions are described both in man and in animals and the indications for its clinical use are set forth in a clear manner. Time has changed the situation slightly, but the fundamental investigations reported in this work are still sound. Brief consideration is given to the treatment of syphilis of the nervous system and to the use of other antibiotic substances. The bibliography is adequate, and the illustrations are good. There is an adequate index. Since the book was written in the midst of active investigations and during a period of stress owing to wartime activities it cannot be considered a final report on the use of penicillin in the treatment of neurologic disorders. The monograph is strongest in the field of neurosurgery and relatively weak in that of the treatment of non-surgical disorders.

Military Neuropsychiatry Volume XXV of the *Proceedings of the Association for Research in Nervous and Mental Diseases* 8th cloth 366 pp. Baltimore: Williams and Wilkins Company 1946 \$6.00.

The subject of military neuropsychiatry is reviewed by over forty-five investigators, most of whom were active participants in World War II. Practically all aspects of the subject are covered by the papers read and discussed at the annual session in December, 1944 of the Association for Research in Nervous and Mental Disease. Since the contributions were written in 1944 the later developments in 1945 are not covered. The volume sets a high standard and is useful as a record of papers in understanding the problems of the war neuroses, combat exhaustion, the psychotherapy of the soldier during conflict, the therapeutic use of drugs in narcosis, craniocerebral injuries and the electroencephalogram, convalescent reconditioning and rehabilitation of discharged veterans. The authors include John E. Whitcomb, Roy R. Grinker, William C. Menninger, Howard P. Rome, Barnes Woodhall and Lewis J. Pollock. As usual in this series of volumes the book is well edited and printed.

Fundamentals of Clinical Neurology By H. Houston Merritt, M.D. Fred A. Mettler, M.D. Ph.D. and Tracy J. Putnam, M.D. 8th cloth 289 pp. with 96 illustrations. Philadelphia: Blakiston Company 1947 \$6.00.

The authors have attempted to give in two sections of the book an outline in some detail of the clinical examination of the nervous system and the methods used in arriving at a correct anatomic diagnosis in cases of structural diseases. In both endeavors they are successful for this is a sound text considering the limitations set up by the three men who collaborated in writing it. One is a clinical neurologist, another an anatomist and the third a neurosurgeon. The book is designed for the use of practitioners and presumably for students of medicine. There are no references to the literature other than an occasional note on the source of an illustration. Although the book contains no material that could not easily be discovered in current texts on clinical neurology the book will prove to be useful. Some of the illustrations being clear line drawings are of particular value. The section on the examination of the nervous system is good and seems suitable to the aim of the book that on anatomic diagnosis which is far in advance of the general practitioner or beginning student, promises to be useful only for postgraduate students in neurology and indeed often goes beyond the material needed for anyone practicing that specialty. Because of this unevenness the book cannot be highly recommended. The authors have put together two unequal parts of clinical neurology overfilling the pages with detailed anatomy much to the detriment of the book as a whole.

A Handbook of Commonly Used Drugs including Certain Measures for the Control of Diseases Peculiar to the Tropics of the Western Hemisphere By Michel Pijon, M.D. and Charles H. Yeager, M.D., Dr. P.H. 8th cloth 198 pp. Springfield, Illinois: Charles C. Thomas 1947 \$7.75.

This small book is largely compiled from personal experience in the use of drugs particularly in the tropics. It is a

condensation of larger works on the pharmacologic basis of therapeutics. Sound and clearly written, the volume should be of use. Although published this year, it is already outdated in certain aspects of the subject. To be of value, such a book should become a continuous product, the authors working on a subsequent edition even before the current one is published. A volume should probably be issued at least every three years. For example, most of the references used in the present book refer to articles published before 1940. In the section on endocrines there is no reference to the literature beyond that date, and yet the title page indicates that the purchaser is justified in expecting the literature to be covered at least through 1946. An even worse record is made in the reference under the therapy of syphilis, for the only work cited is one issued by the same publisher, an edition of 1933. This book, therefore, although valuable and well written, needs complete revision to bring it up to date.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Standard Methods of the Division of Laboratories and Research of the New York State Department of Health. By Augustus B. Wadsworth, M.D. With a foreword by Gilbert Dalldorf, M.D. Third edition. 8°, cloth, 990 pp., with 109 illustrations. Baltimore: Williams and Wilkins Company, 1947. \$10.00.

This third edition of a standard reference work has been revised to include changes and additions made from 1939 to January 31, 1945, when Dr. Wadsworth retired from service. Changes will be noted in practically all sections of the text. A complete revision has been made in the routine methods for the serodiagnosis of syphilis. An outstanding change is the substitution of a new antigen composed of cardiolin, lecithin and cholesterol for the cholesterolized alcoholic extract of beef heart that had been in use for several years. Certain methods in the fields of biochemistry and biophysics have been revised, and new procedures, as well as a new chapter on biologic assay, have been added. In the preface Dr. Wadsworth has given a brief history of the organization under which the methods outlined in the book have been formulated. The volume is recommended as a reference work for all medical laboratories and libraries.

Rehabilitation through Better Nutrition. University of Cincinnati Studies in Nutrition at the Hillman Hospital, Birmingham, Alabama. 8°, cloth, 94 pp., with fifty illustrations, some in color. Philadelphia: W. B. Saunders Company, 1947. \$4.00.

This monograph summarizes the work carried on successfully since 1930 on persons suffering from deficiency diseases and treated by long-term nutrition therapy. It points out that malnourishment usually develops over a period of months or even years and that adequate results from nutritive therapy necessitate long treatment in many cases. From 1930 to 1936 the author studied 278 patients in Ohio with lesions typical of pellagra, beriberi or scurvy. In the Birmingham Clinic 914 patients suffering from various deficiency diseases were selected for study. These patients were afflicted with the vitamin deficiencies, including pellagra and scurvy, the various anemias with nutritive failure, non-tropical sprue and protein deficiency.

Emphasis is placed on accurate diagnosis, and the first part of the monograph is devoted to a discussion of the various diseases from this point of view. A total of 10,851 persons were examined in the clinic from 1936 to 1945, and no evidence of nutritive failure was found in 5140 cases. From the remainder 914 patients with general nutritive failure severe enough to keep them from work were selected. At the final check-up examination in 1945, 21 were not available for various reasons, and the final study was therefore based on 893 cases. It is interesting that the Whites outnumbered the Negroes about 11 to 1, although the population of the community was equally divided.

All the patients included in the study improved promptly under the special treatment, gaining strength and weight, and were able to return to work, which they continued regularly.

The treatment consisted essentially of a high-calorie diet, supplemented by proteins, vitamins and minerals.

The principles of therapy used successfully in these cases were as follows: conditions causing excessive requirements were removed or relieved whenever possible, symptomatic treatment and therapy for coexisting diseases were given, it was made certain that the patient consumed daily a diet that supplied 3000 to 4000 calories, 120 to 150 gm. of protein and liberal amounts of minerals and vitamins, and therapeutic substances, such as dried brewer's yeast powder, liver extract and synthetic vitamins, were administered in sufficient amounts to correct the deficiency. It cannot be expected that these principles will be effective if the diagnosis is not precise or if the therapy is not persistently applied.

The text is well documented with tables, charts and case histories. The illustrations are excellent. A list of references concludes the text. The volume is well published in every way and is recommended for all medical libraries and to all physicians interested in deficiency diseases.

Diseases of the Nervous System. By F. M. R. Walshe, M.D., D.Sc., F.R.C.P. (Lond.), F.R.S., physician-in-charge, Neurological Department, University College Hospital, London, and physician, National Hospital for Nervous Diseases. Fifth edition. 8°, cloth, 351 pp., with 59 illustrations. Baltimore: Williams and Wilkins Company, 1947. (Printed in Great Britain.) \$4.50.

The soundness and popularity of this small textbook is attested by the need of five editions in six years. The text has been brought up to date. The chapters on intracranial tumors and cerebral vascular disease have been rewritten. The volume is printed with a good type on good paper and, for the first time since the war, has wide margins pleasing to the eye.

NOTICES

AMERICAN ASSOCIATION ON MENTAL DEFICIENCY

The Northeastern Section of the American Association on Mental Deficiency will hold a meeting at the Wassaic State School, Wassaic, New York, on Saturday, October 18. After inspection of the school, followed by luncheon at 12:30 p.m., a regular meeting will be held.

PROGRAM

- An Analysis of the Relationship of the Moron Group to State School Training. Drs. Ernest S. Steblen and Joseph E. Rosenfeld.
- Social Service in the Realm of Mental Deficiency. Patricia F. Morgan.
- Occupational Therapy with Mental Defectives. Percy H. Larrabee.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING THURSDAY, OCTOBER 16

- FRIDAY, OCTOBER 17
 - *9:00-10:00 a.m. Gastritis. Dr. Seymour Gray. Joseph H. Pratt Diagnostic Hospital.
 - *10:00 a.m.-12:00 m. Medical Staff Rounds. Peter Bent Brigham Hospital.
- MONDAY, OCTOBER 20
 - *12:15-1:15 p.m. Clinicopathological Conference. Peter Bent Brigham Hospital.
- TUESDAY, OCTOBER 21
 - *12:15-1:15 p.m. Clinicoradiological Conference. Peter Bent Brigham Hospital.
- WEDNESDAY, OCTOBER 22
 - *9:00-10:00 a.m. Uterine Retrodisplacements. Dr. George A. Bear. Joseph H. Pratt Diagnostic Hospital.
 - *12:00 m. Grand Rounds and Clinicopathological Conference (Children's Hospital). Amphitheater. Peter Bent Brigham Hospital.

*Open to the medical profession.

CLINICAL SIGNIFICANCE OF MALIGNANT NEOPLASMS OF THE THYROID GLAND*

WALTER F. ROGERS, JR., M.D.,† SAMUEL P. ASPER, JR., M.D.,‡ AND ROBERT H. WILLIAMS, M.D.§

BOSTON

THE value of extirpating goiters, particularly nodular ones, for the prevention of malignant neoplasms of the thyroid gland has been the subject of considerable discussion for many years. Opinions have ranged from a conservative attitude to one of removing all goiters containing nodules, whether single or multiple.^{1,2} In the presence of these divergent opinions, the frequency with which prophylactic thyroidectomies should be performed needs evaluation.

There are numerous reports in the literature concerning the incidence of malignant neoplasms of the thyroid gland.¹⁻⁷ In two recent reports the incidence of carcinoma was particularly high, Cole et al.³ stating that the incidence was 17.1 per cent in patients with nontoxic nodular goiters, including those with single or multiple nodules, and 7.2 per cent in all nodular goiters, toxic and nontoxic. Such statistics raise an enormous problem if thyroidectomy is to be advocated for all people with nodular goiters, particularly when one considers that in an endemic area the incidence of nodular goiters has been shown to be 80 per cent in autopsy material.³ Even in nonendemic areas, such as the New England seaboard, Schlesinger and his associates⁴ found thyroid nodules, 1 cm. or more in size, which should be clinically palpable, in 82 per cent of cases at autopsy. Using the figures of Cole et al.,³ one might then expect that from 5 to 13 per cent of the people living in an endemic area would suffer from carcinoma of the thyroid gland and that in a nonendemic area the incidence would be from 0.5 to 1.0 per cent.

These hypothetical data show wide discrepancies from actual figures, for in two large series of routine autopsies thyroid carcinoma was found in 1.04 per

cent³ and 1.07 per cent⁴ in endemic areas and in 0.095 per cent³ and 0.109 per cent⁴ in nonendemic areas. In 74,335 cases at autopsy in the United States and Europe, tabulated by Wilson,⁴ the incidence was 0.26 per cent.

Thus, diagnoses of malignant neoplasms of the thyroid gland appear to be frequent in surgical specimens but rare in clinical and autopsy material. The advisability of removing all nontoxic nodular goiters to eradicate a few potentially cancerous glands should be critically considered along with the mortality and complications resulting from these operations. In addition, the actual effect of so-called "prophylactic surgery" on malignant neoplasms of the thyroid gland should be evaluated.

To help clarify this problem, we reviewed the records of patients with goiter admitted to the Boston City Hospital, the Johns Hopkins Hospital, and the Massachusetts General Hospital in twelve-year (1931-1942), five-year (1940-1944) and eight-year (1937-1944) periods, respectively. The clinical course and pathological lesions in cases of malignant neoplasm of the thyroid gland, diagnosed histologically on autopsy or surgical material, were analyzed. These patients have subsequently been followed for from one and a half to ten years. In addition, the records of 431 patients who had undergone operations⁵ for nonmalignant, nontoxic goiter were studied to determine the mortality and complications of this operation.

The large size and location of these general hospitals and the cross section of patients treated should give a good indication of the significance of thyroid cancer in a nonendemic area.

The total number of admissions to the three hospitals in the periods analyzed was 544,918, and goiters were observed in 3221 cases (Table 1). This incidence of goiter, 0.59 per cent, was extremely low and is best explained by the fact that the cases were taken from all the services of large general hospitals and that the neck was not carefully examined in all patients. Table 1 also presents the number of

*These operations were performed at the Boston City and Johns Hopkins hospitals.

nodular and diffuse goiters and the incidence of thyrotoxicity

A pathological diagnosis of malignant neoplasm of the thyroid gland was made in 64 cases, or in 1.99 per cent of all the patients with goiter. Ten additional cases of what appeared to be far-advanced

Of the 64 patients, 76 per cent were females, and 24 per cent were males. This ratio of 3:1 is lower than the usual ratio in nonendemic areas, which is estimated to be 6:1 or 7:1.⁸

The patients complained of a variety of symptoms (Table 2). Fifty-five patients, or 86 per cent, with

malignant neoplasms of the thyroid gland were not proved histologically, inclusion of these cases makes an incidence of 2.29 per cent in patients with goiter. In the following analysis of cases only those with a

malignant neoplasm of the thyroid gland noted a mass or enlargement of the neck. Further elucidation of the history of the mass, however, was important. In the charts of the 55 patients who had noted a mass in the neck, there was a definite statement in 43 cases regarding whether the patient or a physician had noticed a change in the size of the mass before admission. Thirty-four, or 79 per cent, of the 43 patients had noticed a recent progressive increase in the size of the goiter.

None of the other symptoms was experienced in more than 20 per cent of the patients. Aside from

TABLE 2 Symptoms in 64 Cases of Malignant Neoplasm of the Thyroid Gland

SYMPTOM	NUMBER OF PATIENTS	PERCENTAGE
Mass or enlargement of neck	55	86.0
Hoarseness	12	18.7
Dyspnea	12	18.7
Dysphagia	9	14.0
Bone pain (metastatic lesions)	8	12.5
Nervousness	7	10.9
Cough	7	9.4
Weight loss	6	9.4
Palpitation	3	4.7
Paralysis of lower extremities (metastatic lesions)	2	3.1
Hyperorexia	1	1.55
Headache	1	1.55
Irritability	1	1.55
Dizziness and faintness	1	1.55
Chest pain	1	1.55

struma, the most frequent symptoms were those of compression of the surrounding structures: hoarseness, dyspnea and dysphagia. Pain in association with metastases to bone occurred in 12.5 per cent of cases. Although a great variety of other complaints were made, these were infrequent and not usually of much aid diagnostically. No patient had symptoms of hypothyroidism.

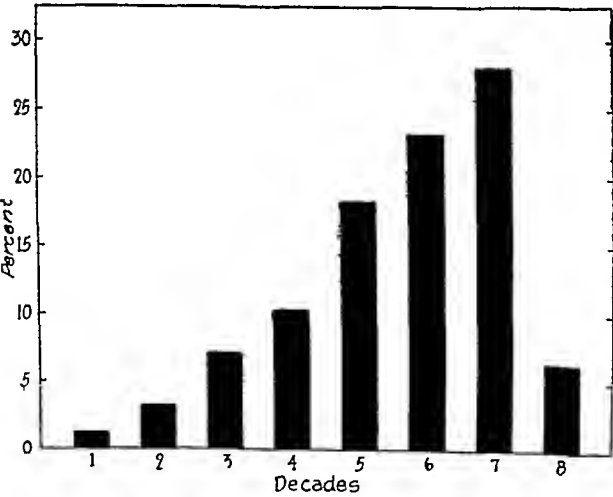

FIGURE 1 Age of the Patient at the Time of Diagnosis

histologic diagnosis of a malignant neoplasm are included.

Cancer of the thyroid gland occurred in each of the first eight decades, with constant increments up to the seventh decade, in which 18 of the 64 cases (28.2 per cent) were found (Fig 1). There were relatively few cases in the eighth decade. Although there was no significant difference between the average ages of the male and female patients, the former being fifty-three and a half and the latter fifty years, there were only 3 males under the age of fifty, whereas 22 females were below that age.

There was a palpable mass in the neck of 63 patients, or 98 per cent. In 47 cases (73.4 per cent) the masses were nodular in contour, and of these, 37, or 78.7 per cent, had a single nodule, 5 cases were multinodular, and in 5 the exact nature of the mass could not be ascertained. The remaining 17 patients had a diffuse type of struma.

The next most frequent physical sign was enlargement of the cervical and supraclavicular lymph nodes, the former occurring in 23.4 per cent of cases and the latter in 7.8 per cent. Other less common signs were paralysis of the vocal cords, increased areas of retromanubrial dullness, masses in the skeleton and neurologic disturbances. No patient had evidence of hypothyroidism.

In an attempt to analyze the extent of metastases, the course, the mortality and the prognosis of pa-

six per cent of cases were classed in the highly malignant group, whereas those designated as low malignancy were relatively infrequent.

Figure 3 presents the extent of involvement in relation to the cervical lymph nodes with subdivision

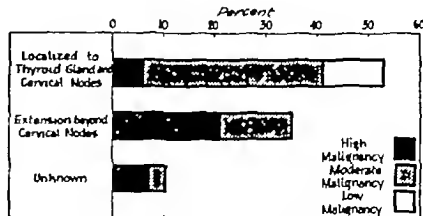

FIGURE 3 Extent of Spread of Neoplasms

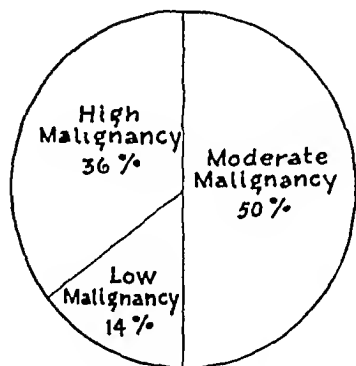

FIGURE 2 Degrees of Malignancy

into the respective degrees of malignancy. In 53 per cent of cases the neoplasm was localized to the thyroid gland and cervical lymph nodes, whereas in 36 per cent it had extended beyond this point. In 11 per cent the extent of the lesion could not be exactly evaluated, and the involvement in such cases was classed as "unknown."

It should be noted that the majority of cases with the neoplasms localized to the thyroid gland and

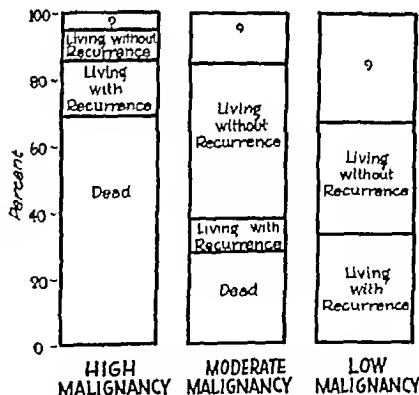

FIGURE 4 Course of Patients in Relation to the Degree of Malignancy

tients with malignant neoplasms of the thyroid gland, it is most important to consider the pathologic classification of these tumors. Lahey, Hare and Warren⁸ reported a classification that is extremely useful, the degrees of malignancy being classified as high, moderate and low. The first group included cases of carcinoma simplex, giant-cell carcinoma, epidermoid carcinoma, fibrosarcoma and lymphosarcoma. In our study the patients with a diagnosis of carcinoma (unclassified) have also been placed in this group. The group classed as moderately malignant consisted of papillary adenocarcinoma, alveolar carcinoma and Hürtle-cell adenocarcinoma. The least and least malignant group was made up of adenoma and papillary cystadenoma with blood-vessel invasion.

In this series the proportion of cases falling into the respective groups is shown, and it may be noted that half the 64 cases occurred in the group considered to be moderately malignant (Fig. 2). Thirty-

cervical lymph nodes were classed as "moderately malignant" (Fig. 3). It is still more striking, however, that all the cases of low malignancy were localized to this region. On the other hand, a relatively small number of the highly malignant lesions were limited to the cervical nodes.

Over half the patients with widespread disease were designated as having highly malignant tumors, and the remainder of cases were classed as moderately malignant. The group classed as unknown were composed mostly of patients with highly malignant tumors. The majority of these patients had large masses in the necks at the time of death, but no permission for autopsy was obtained and the extent of the disease could not be accurately determined.

The mortality was 37.5 per cent, the maximum time of follow-up study being ten and the minimum one and a half years. Of the remaining patients

number living with and without recurrence was equal. As the degree of malignancy declined, less was known about the fate of the patients, probably owing to the fewer symptoms in the patients with more benign lesions, who failed to return for follow-up study.

The duration of goiters before the diagnosis of cancer and the duration of the lesions after diagnosis in patients with highly and moderately malignant tumors is shown in Figure 5. Some patients with highly malignant neoplasms had long-standing goiters, but a large number had goiters of less than one year's duration. In the patients with moderately malignant lesions the goiters were of longer duration, and 15 patients, or 55.5 per cent, had goiters ranging from three to forty years. Likewise, the duration of the disease after the diagnosis had been established was usually less than two years in the highly malignant cases, whereas that in the moderately malignant cases was usually longer than two years. The duration in cases of malignant neoplasm was determined only in the patients who had died or were living with recurrence. Consequently, there is a discrepancy in the number with moderately malignant tumors, because many of these patients are living without recurrence.

To emphasize the varied course that malignant neoplasms of the thyroid may pursue, the following brief abstracts of case reports are presented.

CASE 1 (BCH 1,011,410) A 52-year-old woman was admitted to the Massachusetts Memorial Hospitals in January, 1941, with the chief complaint of a mass over the right eye of 5 months' duration. There was no history of previous goiter. Physical examination revealed a firm mass, 2.5 by 1 cm in diameter, over the right eye, and a nodule protruding upward from beneath the manubrium of the sternum that was thought to be an adenoma of the thyroid gland. The substernal nodule and a portion of the cranial nodule were removed. The histologic diagnosis of the former was small-cell carcinoma arising from an embryonal adenoma, and the mass in the cranium was reported as metastatic carcinoma of the thyroid gland. The patient was then transferred to the Boston City Hospital, where the skull lesion was resected. After operation, she made an uneventful recovery and was well for 5 years, when there was evidence of recurrence of the tumor in the skull. X-ray therapy effected some regression of the lesion. Otherwise, the patient has remained in good health.

CASE 2 (MGH 161,672) In 1928 a 53-year-old woman was admitted to the hospital complaining of a mass at the medial end of the left clavicle. This was removed and was diagnosed as a carcinoma arising in the thyroid gland. After the excision, the patient did well for 11 years, when she began to complain of hoarseness and swelling of the neck, accompanied by pain in the right clavicle and chest. Physical examination at that time revealed a pulsating tumor mass, the size of a hen's egg, at the medial end of the right clavicle. In addition, there were some small nodules surrounding the mass. A biopsy specimen, obtained by needle, was diagnosed as a rapidly growing fetal adenoma, and an x-ray film of the chest was consistent with metastatic cancer. The patient was given x-ray therapy to the right side of the neck and upper mediastinum, with a decrease in the size of the masses in both areas. General improvement followed, and for the next 5 years the patient remained well except for slow growth of the mass in the right side of the neck. At the end of that period she also had pain in the right arm and a destructive lesion in the ilium. She received x-ray therapy to the

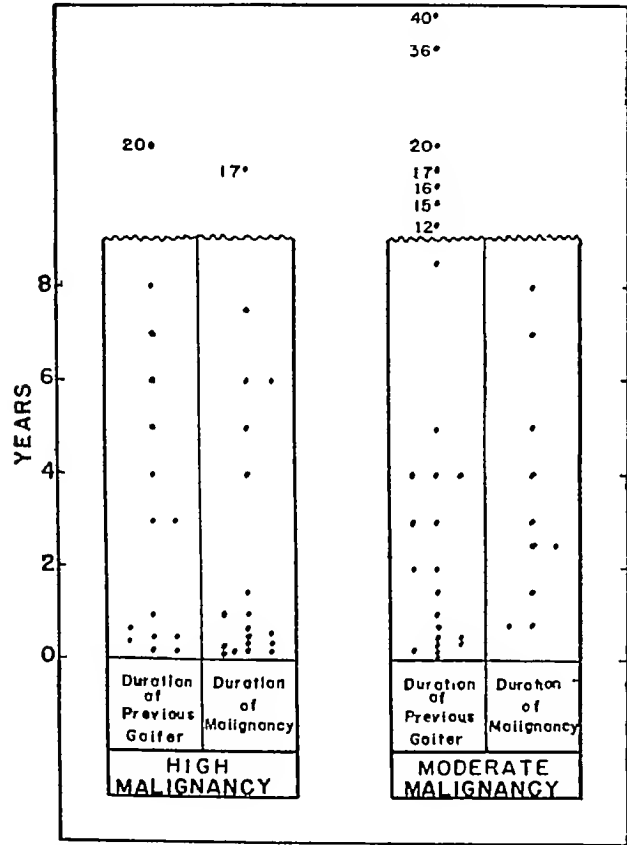

FIGURE 5 Duration of the Goiter previous to the Diagnosis of Malignancy and the Duration of the Malignancy in Patients Who Died or Were Living with Recurrence

15.5 per cent are living with recurrence, 31.2 per cent are living without recurrence, the fate of 12.5 per cent is unknown, and 3.3 per cent died of intercurrent disease. More revealing, however, is the course of the patients in relation to the degree of malignancy (Fig 4). It is seen that 69 per cent of patients with highly malignant tumors are dead and that 17.4 per cent of the others had a recurrence of the disease. In the moderately malignant group, the largest share are living without recurrence, whereas 38 per cent are dead or living with recurrence. Among those with tumors of a low degree of malignancy, there were no deaths, but the

mass in the neck and to the lesion in the ilium without any noticeable clinical improvement. Five months later she died at home, 17 years after the initial diagnosis of carcinoma had been made.

These cases illustrate the long course that carcinoma of the thyroid gland may take, despite the presence of widespread metastatic lesions.

On the other hand, some patients pursued a rapidly fatal course as in the following case.

CASE 3 (M.G.H. 466,945). A 58-year-old man entered the hospital complaining of hoarseness and headaches of 3 months' duration, accompanied by weight loss. There was no history of goiter. Physical examination showed a swelling of the right side of the neck, with a hard irregular mass involving the thyroid gland and extending superiorly and attached to the deep structures. In the hospital he rapidly became worse and shortly after admission contracted an upper respiratory infection followed by pneumonia and death. Autopsy revealed a small-cell carcinoma of the thyroid, with metastatic lesions in the brain, kidneys, adrenal glands and cervical lymph nodes. The entire course of the illness was less than 4 months.

The correct diagnosis was made clinically, or was suspected, in 31 (48 per cent) cases in this series. As would be expected, the correct diagnosis was made more frequently in patients with highly malignant tumors. In the cases in which a correct clinical diagnosis was made 48.5 per cent of patients are dead, whereas in those in which the diagnosis was benign lesions of the thyroid gland, 24 per cent are dead.

Thyroid cancer accompanying thyrotoxicosis is considered rare. In 168 cases of thyroid cancer Ward¹ found 1 case of carcinoma in "a diffuse toxic goiter." Cnle¹⁸ observed 1 case of hyperthyroidism in 249 cases of malignant thyroid neoplasm, and Means⁴ stated that thyrotoxicosis might almost be considered insurance against cancer of the thyroid gland.

Five (7.8 per cent) of the 64 patients with malignant thyroid neoplasms had thyrotoxicosis. These cases occurred among 1308 patients admitted with hyperthyroidism during the respective time intervals reviewed, making an incidence of malignant neoplasms of the thyroid gland among thyrotoxic patients of 0.38 per cent. In none of the 5 cases was cancer suspected, and all patients had thyrotoxicosis at the time of operation. All the patients were in the sixth and seventh decades, however, and all were women. The degree of thyrotoxicosis was variable, since 3 cases were considered moderate, 1 severe and 1 mild. Two patients had diffusely enlarged glands without nodules, 2 had diffusely enlarged glands with single nodules, and the remaining case had nodular enlargement of the thyroid gland. The pathological picture in these cases was varied, since 3 were diagnosed as carcinoma (unclassified), 1 as giant-cell carcinoma and 1 as cystadenocarcinoma. The patient with cystadenocarcinoma is living without evidence of recurrence, whereas the patient with the giant-cell carcinoma had a recurrence of the disease, although at present she is in fairly good health. Of the 3 patients with

unclassified carcinoma 1 died with extensive metastases, and the remainder are apparently well despite the fact that the surgical specimens showed invasion of the veins with tumor in 1 case and the presence of a metastatic lesion in a cervical lymph node in the other.

Since thyroidectomy is frequently advocated for "prophylaxis" against cancer, it is of particular interest to determine the effectiveness of this principle in patients in whom there was no clinical suspicion of cancer before operation.

These patients may be divided into two groups: those who, so far as could be ascertained, had no evidence of neoplastic disease at the time of initial operation and who later developed cancer, and those who were not suspected of having malignant lesions until the specimens had been examined by the pathologist.

The first group is composed of 7 patients who had similar clinical courses in that they had had operations for a goiter at some previous date. This operation was followed by a recurrence of the mass, which at a second operation proved to be the site of a malignant process. In 5 patients the neoplastic disease was found twelve, thirteen, sixteen, twenty-four and thirty-four years after the initial operation. Adenocarcinoma was noted in 3 patients, and papillary adenocarcinoma in the other 2. Two patients died of intercurrent disease, 2 are living without recurrence, and 1 is living with a recur-

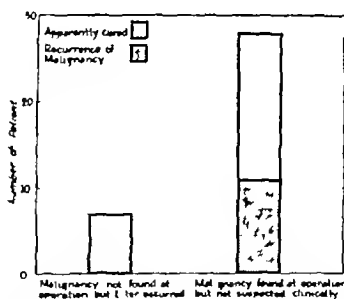

FIGURE 6. Patients in Whom a Malignant Neoplasm Was Not Suspected but in Whom a Thyroidectomy Was Performed

rence of the disease. It might be said that these were cases of low-grade malignancy and that the initial operation had been inadequate or that the surgical specimen was not examined carefully enough. This is granted, since in some cases there was no way to determine how thoroughly the initial specimen had been examined. This does not negate the fact, however, that these patients had carcinoma despite prophylactic surgery, and there is reasonably

good evidence that malignant lesions had not been present at the initial operations

An illustrative case is the following

CASE 4 (BCH 906,993) A 62-year-old woman entered the hospital because of recurrent masses in the neck. Twelve years previously she had had a resection of an adenoma at the Lahey Clinic, the specimen having been diagnosed as papillary cystadenoma. Twelve and 14 years, respectively, after operation she entered the Boston City Hospital for recurrent masses in the neck, ranging from the size of a pea to that of a golf ball. These nodules were removed and each time were found to be papillary adenocarcinoma. On the last hospital admission, 16 years after the initial operation, she was admitted for bloody stools, and a diagnosis of carcinoma of the rectum was made. She still had a nodule in the neck, 4 cm in diameter. An abdominal laparotomy and resection of the rectum were advised, but the patient refused operation. She later died at home, apparently from carcinoma of the rectum.

Of the remaining patients in this group, 1 underwent the extirpation of a thyroglossal-duct cyst, and ten months later a mass recurred, was assumed to be a recurrent thyroglossal duct cyst and at operation was found to be a papillary adenocarcinoma of the thyroid gland, the other patient was operated on for an adenocarcinoma of the thyroid gland nine months after the removal of a fetal adenoma. It seems probable that at the time of the first operation each of these patients harbored a malignant neoplasm that was overlooked.

The second group is composed of the 28 patients who were not suspected of having malignant neo-

in mind that the complications in these cases were probably more frequent than those in a series of cases in which all goiters were routinely removed.

There were 5 fatal cases, or a mortality of 11.6 per cent. The majority of these cases, however, had features that greatly increased the hazard of operation. Thus, 2 patients had dyspnea, dysphagia and pressure symptoms, caused in 1 case by a Riedel's struma and in the other by a large adenoma (10 x 10 x 15 cm) with abscess formation. The glands were removed with great difficulty in both cases. The first patient died on the fourth postoperative day, with an autopsy diagnosis of bronchopneumonia and damage to the recurrent laryngeal nerves, and the second died on the first postoperative day with a clinical diagnosis of pulmonary embolism. A third patient was found to have substernal extension from a nodular goiter and died on the first postoperative day, having become flushed, toxic and delirious. The clinical impression was that the patient died of pneumonia, but autopsy was not performed.

A seventy-three-year-old woman with a 7.5-cm nodule in the right lobe died on the third postoperative day of pneumonia and cardiac failure. Another female patient, aged sixty-one years, had a nodular goiter removed without great difficulty, but it was noted at operation that the trachea was the size of the surgeon's fifth finger. Postoperatively, the patient had respiratory distress and difficulty in speaking, and she died during the second postoperative day.

The various complications of operations on patients with nontoxic goiter are presented in Table 3, of these patients, 15.3 per cent suffered from one or more operative complications, the most significant of which consisted of 13 cases of vocal-cord paralysis, 7 of hypoparathyroidism and 5 of hypothyroidism. Complications such as massive hemorrhage, hematomas and anesthetic accidents, of course, did not involve long-term disability, but at the time caused a definite threat to life.

DISCUSSION

It is admittedly difficult to determine when a goiter contains a malignant neoplasm particularly a neoplasm that arises in a previously existing adenoma or one of low malignancy. Because of this problem, it has been suggested that every nodular goiter should be "prophylactically" removed.^{1,2} This type of reasoning is not regarded as justified, particularly in the light of the figures presented above. Some selection of cases is considered possible, and prophylactic surgery is not reducing deaths from malignant neoplasms of the thyroid gland as much as has been implied.

We have found the clinical incidence of malignant neoplasms of the thyroid gland to be low—much lower in fact than one would expect from previously cited figures on surgical specimens.^{2,7}

TABLE 3 Complications of Operations in 431 Cases of Nontoxic Goiter

COMPLICATION	NO. OF CASES	COMMENT
Vocal-cord paralysis	13	Four patients had large glands, and 1 had Hashimoto's disease
Wound infection	11	—
Hoarseness	10	Duration of 3 days to 2 months
Marked swelling of neck, with fever	9	—
Hypoparathyroidism	7	Transient in 5 cases, duration of 1 year or longer in 2.
Hypothyroidism	5	One patient had chronic thyroiditis
Hematoma	3	—
Postoperative hysteria or delirium, or both	3	—
Massive hemorrhage	2	—
Dysphagia	2	Transient but severe
Anesthetic accident	1	Cardiac arrest, restoration of cardiac function with intracardiac adrenalin

plasms until after histologic examinations of thyroid tissue had been made (Fig. 6). Among these there were 11 who had a recurrence of the tumor, with 6 subsequent deaths.

The two groups of cases discussed above lend support to the statement of Hertz¹¹ that after multiple operations on thyroid glands, cancer has developed despite the "prophylactic surgery."

To evaluate the principle of the extirpation of goiters, the complications resulting from such a procedure were determined by a review of the charts of 431 patients who had had a thyroidectomy for nontoxic goiters, diffuse or nodular. It was borne

In this report, particular stress has been placed on the pathological lesion and its degree of malignancy because the clinical course of the patient depends so much on this factor. The majority of patients who died of malignant neoplasms of the thyroid gland or had widespread extension had tumors that were classed as highly malignant. These highly malignant tumors, as emphasized by Clute and Warren,¹² were usually characterized by a sudden appearance of a mass in the neck, although at times they arose in a previous goiter, and pursued a rapidly fatal course. Such tumors are rarely removed completely by prophylactic surgery.

On the other hand, in the cases classed as tumors of moderate or low malignancy there were few deaths (none in the latter), and the results of treatment were fairly satisfactory. Even when clinically suggestive of malignancy, these tumors are often amenable to treatment. This point of view is likewise held by Pemberton.¹³ These tumors, then, with a better prognosis, are frequently said to be "cured" by prophylactic surgery. When one considers, however, that even when a benign tumor of the thyroid gland or a clinically unsuspected malignant neoplasm is removed, development or recurrence of a malignant neoplasm is not infrequent, the value of routine prophylactic surgery on all nodular thyroid glands becomes less impressive.

As in other reported series, the patients in whom a correct diagnosis was made had the highest mortality rate. This does not necessarily mean that prophylactic surgery would have obviated this, because as pointed out above, the majority of these patients had highly malignant types of tumors in which the onset and course of the disease was of short duration, despite various types of therapy.

The incidence of operative complications in cases of nontoxic goiters should also be considered. If the 431 cases in this report are considered to be an average illustrative example, it is seen that many operative complications and even death may occur. Although it is said that extirpation of nontoxic goiters and adenomas should be without risk, this seems to be a goal more sought after than actually obtained, particularly when applied to all clinics and hospitals.

Single nodules or masses in the thyroid gland are the most frequent site of malignant lesions. This has been particularly emphasized by Lahey.¹⁴ The greatest number of patients studied likewise had a single nodule or mass as the site of the neoplasm. Thus, it seems that many of these single nodules should be removed, particularly in young people, for in a nonendemic area nodules are rare below the age of thirty,⁶ and should arouse suspicion of a malignant lesion. On the contrary, it seems unnecessary to remove all multinodular glands because they are infrequently the site of cancer and so prevalent, even in nonendemic areas, that the disadvantages of removal outweigh the advantages.

Some pathologists have considered nodules in the thyroid gland to be "almost physiological," especially in women after the age of fifty.⁶

Certain signs in a gland with one or more nodules, however, are indications for removal of the nodule. They are any increase in size, especially in the absence of thyrotoxicosis, and any suggestion of increased firmness or fixation of the surrounding tissue. The first sign is probably the more important because the other connotes more extensive involvement. Multinodular goiters may well be treated conservatively but deserve careful observation.

Of the patients with malignant neoplasms of the thyroid gland 7.8 per cent had thyrotoxicosis. This figure is slightly higher than that in other reported series.^{1, 15} It is still to be noted, however, that cases of malignant neoplasm accompanying thyrotoxicosis are rare, for in 1303 cases of thyrotoxicosis there were 5 patients (0.38 per cent) with malignant neoplasms.

What effect the treatment of thyrotoxicosis with thiouracil will have on thyroid cancer must await future evaluation. Bielschowsky¹⁶ has shown that simultaneous administration of 2-acetyl-amino-fluorine and allyl-thiourea produced adenomas and malignant neoplasms in the thyroid glands of rats, whereas either of these drugs used alone did not produce the neoplastic lesions. We have administered 2-acetyl-amino-fluorene and thiouracil simultaneously to a series of 12 rats, and although malignant tumors of the breast and other organs developed in 8, the only detectable lesion in the glands was hyperplasia. To date, there is no clinical evidence that thiouracil is a predisposing factor or that it has increased the incidence of cancer.

Regarding "prophylactic surgery" for nodular or diffuse goiter in the prevention of thyrotoxicosis, we believe that this complication can be well treated, should it arise, with antithyroid drugs and surgery.

SUMMARY

The total number of patients admitted to the Boston City Hospital, the Johns Hopkins Hospital and the Massachusetts General Hospital in periods of twelve, five and eight years, respectively, was 544,918. Among these patients there were 3221 with goiters and 64 with a histologic diagnosis of a malignant neoplasm of the thyroid gland.

The clinical picture and the course of the patients with malignant thyroid neoplasms are discussed, with particular reference to the types of pathological lesions and their degree of malignancy.

It was found that in clinical and autopsy material malignant neoplasms of the thyroid gland were infrequent. The majority of patients dying of malignant lesions had highly malignant tumors that were generally of rapid onset and of short

duration, and in these patients "prophylactic" surgery had rarely been performed

Patients with thyroid tumors of lesser degrees of malignancy do not have a hopeless prognosis. Sometimes, even with apparently widespread metastases, they live for more than ten years.

It is not believed that all nodular goiters should be removed. Despite "prophylactic" surgery on benign or clinically unsuspected malignant goiters, lesions may later develop or frequently recur. Moreover, operations on patients with nontoxic goiter are associated with a significant number of complications and are sometimes fatal.

Single nodules, particularly in young people, should in most cases be removed, and any nodule showing an increase in size, in the absence of thyrotoxicosis, or in firmness or fixation should be extirpated.

We are indebted to Drs. James Means, Oliver Cope and Benjamin Castleman, of the Massachusetts General Hospital, and to Dr. Alfred Blalock, of the Johns Hopkins Hospital, for permission to study the case records at those hospitals.

USE OF PENICILLIN IN THE TREATMENT OF CARRIERS OF BETA-HEMOLYTIC STREPTOCOCCI AMONG PATIENTS WITH RHEUMATIC FEVER

JESSAMINE R. GOERNER, M.D.,* BENEDICT F. MASSELL, M.D.,† AND T. DUCKETT JONES, M.D.‡

With the Technical Assistance of Mary Meyeserian

BOSTON

THE danger of hemolytic streptococcus respiratory infection to persons who are susceptible to rheumatic fever is well recognized. Since with present knowledge there are inherent difficulties in evaluating the innocuousness of a given strain, every carrier of beta-hemolytic streptococci must be considered a potential menace to a population of rheumatic-fever patients. Prolonged isolation of such carriers is inadvisable from the psychologic standpoint and is usually impracticable. Hence, means of abolishing the carrier state are desirable.

During the administration of sulfonamides to carriers the throat cultures become negative for hemolytic streptococci in some cases, whereas in others the cultures, although remaining positive, usually yield only small numbers of the organism. In most cases, however, when therapy has been discontinued, nose or throat cultures again become strongly positive.¹⁻¹¹

Many investigators have found penicillin to be a more effective agent than sulfonamides for the treatment of hemolytic streptococcus respiratory infections. From these reports it also seems that during penicillin therapy hemolytic streptococci disappear from the nose and throat in nearly all cases. After the discontinuation of treatment the organisms have reappeared in a varying proportion of the reported cases, depending apparently on the dose of penicillin and the number of days of treatment.⁷⁻¹⁸

With a view to preventing the spread of hemolytic streptococci from one patient to another, since November, 1945, penicillin has been administered to all patients at the House of the Good Samaritan found to have positive throat cultures. The following brief extracts of cases observed at the hospital in the early autumn of 1945 illustrate the need for the elimination of beta-hemolytic streptococci from the upper respiratory tract of carriers.

CASE 1. W. J., a 5-year-old boy with rheumatic heart disease and subsiding rheumatic fever, had been a patient at the House of the Good Samaritan since July, 1945—an interval of four months. Fifteen of the twenty-one cultures of the throat taken from August 1 to November 7 yielded Group A beta-hemolytic streptococci, Type 30. The child had large tonsils and cervical adenopathy. Twice during September and October he developed a profuse purulent nasal discharge, which also yielded beta-hemolytic strepto-

cocci on culture, although there were no elevation of temperature and no other associated signs of illness. The serologic type of the isolated streptococci did not change.

On October 1 another small boy (Case 2) was admitted with the diagnosis of rheumatic fever, rheumatic heart disease and chorea. Three successive daily routine admission cultures and subsequent weekly ones were negative for hemolytic streptococci until October 25, when the patient was moved into a large ward in which the only other occupant was the patient discussed above. The distance between the beds was about 20 feet, and neither child was permitted out of bed. Cultures of the throat in Case 2, taken on October 29 and 30, were positive (1+ and 4+,* respectively) for

The other girl, M. S., was admitted late in August, looked well and had no signs or symptoms of rheumatic fever except for a subcutaneous nodule and intermittent elevation of the erythrocyte sedimentation rate. The throat cultures contained no hemolytic streptococci. In early October J. R. was allowed out of bed for brief intervals with resulting direct contact with her wardmates, one of whom, M. S. developed throat cultures lightly positive for hemolytic streptococci, Type 28, with no signs or symptoms of acute streptococcal infection and with notable absence of fever. Within 2 weeks of the date of the first positive culture however erythema marginatum appeared and was followed by significant elevations in the antistreptolysin O titer and sedimentation

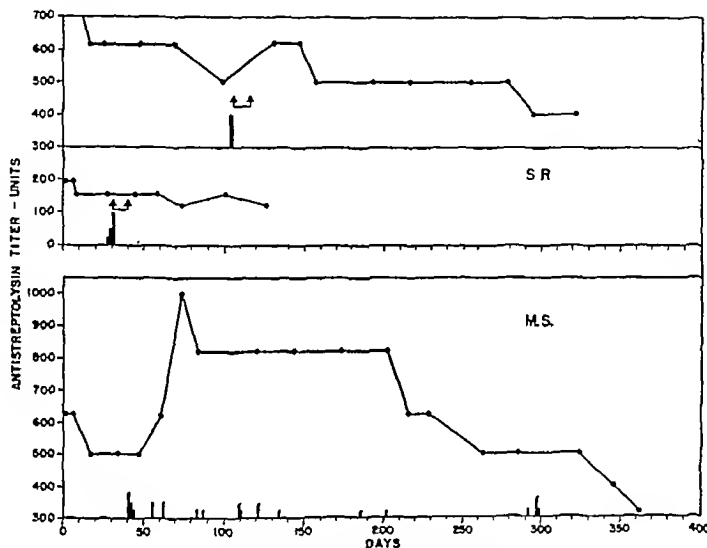

FIGURE 1 Antistreptolysin Titers

The black columns represent positive throat cultures the height of the column corresponding to the heaviness of the growth. The intervals of penicillin therapy are indicated by the arrows.

Group A beta hemolytic streptococci Type 30 and on October 31 this child developed severe tonsillitis, with a maximum temperature of 105°F. Penicillin treatment was initiated within 4 hours of the onset of the clinical illness and continued in dosages of 10 000 units every 2 hours, being given intramuscularly for 10 days to a total of 1 200 000 units. A culture taken 18 hours after the beginning of the therapy as well as all subsequent ones, contained no beta hemolytic streptococci. The acute illness subsided promptly and no recrudescence of rheumatic fever occurred. The other occupant of the room received penicillin in the same dosage for the same length of time and although the culture became negative for hemolytic streptococci, the lymphadenopathy and tonsillar hypertrophy persisted.

CASE 3. J. R. one of two 7 year-old girls who occupied adjacent beds in a large ward, had been a carrier of beta hemolytic streptococci Type 28, as well as, occasionally a second untypable (X) strain, during the 7 months since admission in April, 1945. Of 43 throat cultures taken during that time, 38 were recorded as 1+ to 4+ with Type 28 predominating.

*Grades 1+ to 4+ represent increasing heaviness of growth of organisms on culture plates.

rate and by the development of many nodules, mild arthralgia, transient tendon contractures, hepatitis, later chorea and auscultatory and electrocardiographic evidence of heart disease including pericarditis. The rheumatic syndrome persisted for months during which the streptococci occasionally reappeared in the throat cultures (Fig 1).

It is apparent that in these 2 cases hemolytic streptococci were transmitted from a chronic carrier to a susceptible person. In 1 case the streptococcal invasion caused a severe clinical respiratory infection, which, however, was not followed by a recurrence of rheumatic fever. In the other case the resulting streptococcal infection, although subclinical, precipitated a recrudescence of rheumatic fever.

PROCEDURE

All patients whose routine throat cultures yielded hemolytic streptococci were followed by means of

cultures taken at least three times a week until the presence of the carrier state was established — that is, until the number of positive cultures was shown to be well in excess of the number of negative cultures, with no tendency to diminish

Any patient suffering from an acute streptococcal infection was placed under treatment with penicillin as soon as the diagnosis was made. A control culture was taken just before the first dose of penicillin. In such cases the treatment was identical with that given the healthy carriers.

Penicillin — in doses of 10,000 units every two hours, day and night, for ten days — was given in-

were given penicillin prophylactically, beginning immediately after operation and continuing until the operative wound was healed and there was no fever.

RESULTS

The primary object of the experiment was achieved in most cases — that is, beta-hemolytic streptococci were eliminated from the throat cultures in 17 of 20 cases for the duration of the post-treatment observation periods, which ranged from twenty* to one hundred and forty-six days (Table 1). Of the seventeen organisms that yielded to treat-

‡Sisters

intramuscularly to a total of 1,200,000 units to all patients in these two classifications.

The organism isolated in each case was grouped and typed by the Lancefield capillary precipitin technic,¹⁹ and its sensitivity to penicillin determined.

Throat cultures were taken three times weekly during treatment, daily from one to two weeks after treatment and then with gradually decreasing frequency to a routine weekly schedule.

Antistreptolysin O titers and erythrocyte sedimentation rates were followed at bi-monthly intervals.

When tonsillectomy was clinically indicated in the penicillin-treated cases, it was performed after the rheumatic fever had subsided and was preceded by several daily throat cultures, the last immediately before operation. Cultures of the open tonsillar fossae were obtained during operation, and the tonsils were sectioned and cultured. The patients

ment, fifteen belonged to Group A, whereas the extracts of two failed to precipitate with A, C or H serums (Cases 14 and 18). In 2 of the 3 unsuccessful cases (12 and 17) the organisms, not of Group A, were also morphologically atypical and weakly hemolytic, in the third, the organism was an untypable strain of Group A, which was unusually sensitive to penicillin in vitro. There was no known factor common to these three organisms by which they differed from the seventeen that yielded to treatment. In 2 patients (Cases 3 and 5) the cultures became positive a second time, but with organisms of types different from those originally recovered.

The downward trend of the antistreptolysin O titer was apparently unaltered by the treatment of chronic carriers with penicillin. In 2 cases of acute streptococcal infection (Cases 2 and 4), each treated

*Infection with a new type of streptococcus appeared on the twentieth post-treatment day in 1 case.

within two days of the appearance of the organism in the throat culture and within four hours of the onset of the clinical illness, there was no significant rise in the antistreptolysin titer (Fig. 1) and no recrudescence of rheumatic fever. In contrast, in another patient, M S., who was not treated because the infection was subclinical, the antistreptolysin titer rose from 500 to 1000 units coincident with the development of multiple signs and symptoms of rheumatic fever. These observations suggest that a careful comparative study of penicillin-treated and untreated cases of streptococcal infection in patients with rheumatic fever should be undertaken.

In each of the 2 cases in which an organism was believed to have been transmitted from one patient to another, the streptococcus recovered from the recipient appeared to be more sensitive to penicillin

other, and in each case in which beta-hemolytic streptococci were found in one or both of these cultures, two additional cultures were obtained at intervals of a few days. Treatment was instituted in the 6 cases in which these preliminary cultures were positive.

Penicillin in beeswax and peanut oil was given to each of the selected patients intramuscularly in single daily doses of 150,000 units for ten days, to a total of 1,500,000 units. Throat cultures were taken at intervals of three or four days, beginning twenty-four hours after the first dose of penicillin—that is, just before the administration of the second dose. Serum penicillin concentrations were determined at specific intervals (Table 2).

These observations were necessarily less complete than those on patients in the House of the

than that of the carrier donor, although it is acknowledged that the differences are within the limits of error. In 1 case the inhibiting concentration of penicillin *in vitro* dropped from 01 to 006 units per cubic centimeter, and in the other, from 003 to 006 units on repeated determinations.

Tonsillectomy was performed in 5 of the treated cases. In each of these, cultures of the throat, tonsillar fossae and sectioned tonsils were negative for beta hemolytic streptococci. It may be noted that the intervals between penicillin treatment and operation ranged from one hundred and twenty-five to one hundred and eighty-five days. It would be of importance to determine whether the complete eradication of hemolytic streptococci from the interior of the tonsils and the other deep tissues of the upper respiratory tract by means of penicillin had any influence on the chronicity of rheumatic fever.

EXPERIENCE WITH SLOWLY ABSORBABLE PENICILLIN

A program similar to that described above was undertaken at a convalescent home,* where repeated rounds of streptococcal infections had been troublesome.

Two sets of throat cultures of patients and personnel were obtained within a few days of one an-

other. Good Samaritan because of the shorter hospitalization periods and the heterogeneous types of cases, as well as the geographical distance of the institution from the laboratory. None of the strains obtained from these patients was classifiable with available typing serums. In 5 cases the cultures remained free of hemolytic streptococci for the duration of the observation period (about one month), in the remaining case the culture again became positive, but whether the organism was of the same or different type could not be determined.

SUMMARY

Eighteen chronic carriers of beta-hemolytic streptococci and 2 cases of acute streptococcal tonsillitis were treated with a total of 1,200,000 units of penicillin each, given intramuscularly during ten days.

In 17 cases the infecting organisms were eliminated permanently from the throat cultures. One Group A streptococcus and two that did not belong to Group A, C or H failed to disappear.

In 5 cases in which tonsillectomies were performed one hundred and twenty-five to one hundred and eighty-five days after treatment, the tonsillar fossae and sectioned tonsils were free from hemolytic streptococci.

*The Wellesley Convalescent Home through the courtesy of Dr. Henry Gallup.

In 2 cases the antistreptolysin O titers did not rise after acute streptococcal infections that were promptly treated with penicillin

Penicillin injections once daily for ten days in slowly absorbable form were observed to be successful in eliminating the beta-hemolytic streptococcus carrier state in 5 of 6 cases

The ability to eliminate beta-hemolytic streptococci from the throats of most patients in close contact with persons who have had rheumatic fever suggests a practical method of protecting the latter group from beta-hemolytic streptococcus infection

It is evident that further observations are needed to ascertain whether prompt penicillin treatment for acute hemolytic streptococcus infections in subjects with rheumatic fever may decrease the likelihood of a recurrence of rheumatic fever

THE VALUE OF THE METHYLENE BLUE TEST IN THE DETECTION OF BILIRUBIN*

C. LAWRENCE HOLT, M.D.†

PORTLAND, MAINE

WHEN Fellinger and Menkes¹ described a modification of Franke's² methylene blue test for bile in the urine, they suggested that certain quantitative potentialities of the test existed. They observed that determinations made on twenty-four-hour collections of urine paralleled blood bilirubin levels to a satisfactory degree. Determinations on individual samples, however, were not reliable, since dilution factors, as represented by varying specific gravities of the urine, affected the depth of color that took place after the addition of methylene blue. The depth of color in their technic represented the basis of quantitative interpretation.

Gellis and Stokes,³ after considerable investigative studies, reported a further modification of the original test. They suggested that it might be used as an aid in the early recognition of bilirubinuria in infectious hepatitis. The authors did not claim to describe an unusually sensitive or accurate test for the presence of bilirubin but rather to suggest that the test could be used for demonstrating bilirubinuria

in working with large numbers of soldiers in the field.

The present investigation was undertaken to determine the accuracy and reliability of the test as judged by civilian medical standards, in an effort to determine whether it has any place in routine laboratory procedures. The technic used was that described by Stokes and Gellis.^{3,4} This consisted of a drop by drop addition, to 5 cc of urine, of an aqueous methylene blue solution (0.2 per cent by actual dye content) from a 1-cc pipette delivering 20 drops per cubic centimeter. If 5 or more drops were necessary to change the green color of the mixture of urine and methylene blue to a blue color, the test was considered positive for bilirubinuria.

Investigators at the Boston City Hospital⁵ found that chrome pigments other than bilirubin gave a greenish color when methylene blue was added and therefore believed that the test was not specific. Other workers had previously made the same observation.^{6,7} Roch,⁷ indeed, offered this lack of specificity as a criticism of Franke's original test. Figge's⁸ criticism was of a similar nature, and appeared in print shortly after Myers⁹ had reported

*From the Evans Memorial Massachusetts Memorial Hospitals, and the Department of Medicine, Boston University School of Medicine.

†Formerly assistant in medicine, Boston University School of Medicine, and fellow in internal medicine, Evans Memorial Massachusetts Memorial Hospitals.

that he had adapted the test as an early demonstration of toxic hepatitis resulting from industrial toxins. Recent spectrophotometric studies made by a group at the Mayo Clinic¹⁰ demonstrated that the color changes involved in the test were unquestionably due to a blending of blue and yellow colors, rather than to some specific chemical reaction

urine is not unusually high. As demonstrated below in detail, the deeper color of the more concentrated urines may give a falsely positive reaction with methylene blue.

Studies of urine in patients receiving more than 600,000 units of penicillin in twenty-four hours gave three borderline and one distinctly falsely

for study because of their present popularity as therapeutic agents. Patients receiving these substances were studied in some detail to determine how much of the substances was necessary to cause a yellowish discoloration of the urine sufficient to give a falsely positive test on the addition of methylene blue.

Studies were first made on a group of 14 patients receiving less than 300,000 units of penicillin in twenty-four hours. Urinalyses showed that the methylene blue test may give reliable results (Table 1), so long as the specific gravity of the

tests, however, were negative. It is apparent, therefore, that both riboflavin and penicillin may give falsely positive foam and methylene blue tests.

The effect on the methylene blue test of concentration of chrome pigments in the urine was clearly demonstrated by a study of samples of urine with varying specific gravities from a patient receiving 900,000 units of penicillin daily. The results are recorded in Table 2. Urines with low specific gravities (1.003 to 1.006) required but 1 drop of

methylene blue to complete the appearance of a blue color. Urines with higher specific gravities (1.015 to 1.017) required 4 drops of methylene blue to give a positive test. Accurate comparisons of the depth

Table 3. The changes in reaction were made by the addition of varying amounts of acetic acid and sodium hydroxide to the specimens of urine to be tested. In 1 case urine from a jaundiced patient was

and Menkes,¹ who demonstrated the influence of specific gravity on the methylene blue test.

The effect of the reaction on the methylene blue test was studied, and the results are reported in

solutions (Table 3), but not enough to be considered a real factor.

To compare the relative sensitivity of the methylene blue and other popular tests for bilirubinuria, determinations of serial dilutions of a specimen of urine from a jaundiced patient were made. The results are recorded in Table 4. The Naumann¹² concentration test is certainly the most sensitive, and may in fact demonstrate the presence of bilirubin in normal urine. The Harrison,¹¹ the Watson¹³ modification of the Harrison and the spot diazo tests,¹¹ although less sensitive than the Naumann concentration test, are reliable and excellent. The foam test, if carried out under daylight and compared with a control urine, is found to be quite sensitive but also extremely nonspecific, since it will give a falsely positive test in the presence of riboflavin, penicillin and quinacrine (Atabrin). All these tests are considerably more sensitive than the methylene blue procedure.

There are three approaches to the problem of determining the actual concentration of bilirubin that must be present for the methylene blue test to be positive. One is to add various known amounts of bilirubin* to urine. Another is to make serial dilutions of urine from a jaundiced patient and to determine the amount of bilirubin present in the greatest dilution giving a positive test. A third method is to determine the total bilirubin content of serum from a jaundiced patient and to determine how much of this serum must be added to measured amounts of urine to give a positive test. It is not the purpose of the present paper to discuss the relative merits or disadvantages of these methods, difficulties and uncertainties are encountered in all of them. Exact quantitative recoveries could not be made when known amounts of bilirubin were added to specimens of urine, regardless of whether bilirubin was added as an alkaline solution, as alkaline chloroform solution¹⁴ or as solution prepared in accordance with the more complicated technic of Grotepass and van den Bergh.¹⁵ The methods for determining the bilirubin content of urines from jaundiced patients were likewise unsatisfactory. Consistent results could not be obtained with Hunter's¹⁶ technic or Godfried's¹¹ modification of it. In the present study a modification of Godfried's technic was devised so that the final result could be determined by the Evelyn colorimeter, but this also proved disappointing. The third method, although it also has certain drawbacks, gave the most satisfactory and consistent results. The methylene blue test, by the use of this method, was positive when 2 or 3 mg per 100 cc (average of 2.5 mg per 100 cc) of bilirubin was present.

Although the methylene blue test is neither specific nor sensitive, it is of definite value in giving a roughly quantitative index of the daily trend of icterus in a jaundiced patient. It obviates the necessity of multiple venipunctures, which are required for blood bilirubin determinations. It is the only test to date for bilirubin that can be quantitated in unit measures—that is, in drops. The recently described semiquantitative test of Watson and Hawkinson,¹⁷ using their modification of the Harrison spot test and a standard color chart, is not so quantitative as the methylene blue test. Daily variations in the methylene blue test can be kept at a minimum by testing prebreakfast specimens (Table 5). In this manner, changes in the specific gravity will not be great. More accurate determinations may be made on twenty-four-hour collections, provided that the urine is kept in a cool, dark place, preferably in a receptacle whose bottom is covered with a thin layer of mineral oil. Penicillin and riboflavin will not interfere with the

daily determinations of bilirubinuria by the methylene blue test, since in most cases the patient will receive a constant dose of these drugs and excrete a constant amount from day to day (Table 6). The procedure is therefore considered to be of definite value.

SUMMARY

Evaluation of the methylene blue test for bilirubinuria has yielded the following results. The test is nonspecific and may give falsely positive results when the urine contains yellow pigments, such as penicillin and riboflavin. The test is not significantly affected by changes in the urinary reaction, but is affected by changes in the specific gravity. The test is less sensitive than the Naumann concentration test, the Harrison, the spot diazo and the Watson modification of the Harrison and the foam tests. The Naumann concentration test, however, may give positive results in normal urines, and the foam test is highly nonspecific. The present study suggests that the methylene blue test is positive when the concentration of bilirubin in the urine is 2 or 3 mg per 100 cc. or more. Although the test is neither highly accurate nor specific, it provides a valuable means for estimating the daily excretion of bilirubin in the urine of jaundiced patients.

MEDICAL PROGRESS

GENERAL PRINCIPLES OF THE LABORATORY DIAGNOSIS OF VIRAL INFECTIONS*

F S CHEEVER, M D †

BOSTON

VIRUSES may be defined as ultramicroscopic agents, usually filterable, that are unable to propagate themselves in the absence of living cells and that are frequently the cause of clinical disease in man. This definition does not set off viruses sharply from certain bacteria, in fact, the current view is that "viruses represent the degenerate descendants of larger pathogenic micro-organisms."¹ Laboratory procedures for the specific diagnosis of disease due to bacterial agents are well known and standardized, and can usually be handled satisfactorily by the average hospital laboratory. The identification of virus agents, which is carried out along the same general lines, is rendered difficult by certain characteristics of these agents. The more important of these properties are as follows:

Virus agents range in size from approximately 10 (as in foot and mouth disease and poliomyelitis) to 250 millimicrons or more in diameter (as in psittacosis). Although a few of the larger viruses may be seen with the ordinary microscope, the great majority are too small for its resolving powers. Typical morphology, staining reactions and so forth, which are important in diagnostic bacteriology, are not yet available for the recognition of most viruses.

Virus agents are obligate intracellular parasites, and multiplication does not take place in the absence of living cells. Thus, for their propagation, recourse must be had to tissue culture, animal inoculation or the use of the developing chick embryo. These methods are complicated, expensive and protracted compared to those available for the culture of bacterial agents.

Although, broadly speaking, the resistance of viruses to various chemical and physical forces parallels that shown by the vegetative forms of the majority of pathogenic bacteria, it is characteristic of many of the former agents that their extracellular survival time is relatively brief except under special conditions. For example, cultures of many pathogenic bacteria retain their viability for long periods under varying conditions of temperature if inoculated on agar slants protected from the effects of evaporation. Such a technic permits the shipping of pathogenic cultures from all parts of the world to central laboratories for identification. Unfortun-

ately, no such easy method is available in the identification of virus agents. To maintain their viability in the absence of actively proliferating tissue cells, one must resort to freezing at -70°C or lyophilization or, less satisfactorily, preservation in 50 per cent glycerol. This makes the problem of transporting or shipping virus agents for any distance a difficult one. This question is discussed in greater detail below.

DIAGNOSTIC PROCEDURES

Diagnostic procedures for viral infections may be discussed under the following general headings: isolation and identification of the virus itself, serologic demonstration of the formation of specific antibodies against a virus during the clinical course of the disease, pathological demonstration of specific inclusion bodies, and skin tests illustrating the development of altered skin sensitivity to a specific virus or some fraction of it as a result of infection with the specific agent.

Although in a few virus diseases it is at least theoretically possible to make a specific diagnosis by several of these methods, in general, only one procedure is used for routine diagnostic work. In the majority of cases the serologic approach is the most practical one. The disadvantage of this method is that the diagnosis is made in retrospect, rather than in the early stages of the patient's illness.

Isolation of the Virus Agent

The isolation of the causative virus agent from a patient and its subsequent identification is usually a costly, laborious and prolonged procedure, hardly practical for use by other than the specialized laboratory. Animal inoculation and injection of the developing chick embryo are the two methods generally used. Mice, hamsters, guinea pigs, ferrets, rabbits and monkeys are the animals most frequently employed.

If the material to be inoculated is uncontaminated by bacterial agents (as in blood or spinal fluid), it may be injected directly into the animal or chick embryo. Material such as tissue is washed with sterile water, weighed and cut into small pieces under aseptic conditions. It is ground in a sterile mortar with sterile sand or alundum and enough buffer solution or broth added to form a 20 per cent

suspension (Physiologic saline solution appears to have a deleterious effect on some viruses) The suspension is centrifuged at a low speed to throw down the coarser particles, and the supernatant fluid is used for injection

In the event that the material to be inoculated is not free of bacterial agents, it must be suitably treated to obtain a bacterium-free inoculum Filtration is effective for this purpose. Berkefeld, Mandler and Seitz filters are often used In each a filter with a pore size sufficiently fine to hold back ordinary bacteria is employed, care must be taken not to reduce the porosity to a point where virus agents of larger sizes would also be held back Other factors as well as particle size are important in determining the filtrability of an agent the amount of positive or negative pressure applied, and the length of time over which it is exerted, the type and reaction of the suspending fluid and the electrical charge of the filter and of the fluid to be filtered. The presence of larger tissue particles in the suspending fluid results in the rapid clogging of the pores, and for this reason the fluid should be cleared first by centrifugation at a moderate speed (3000 to 4000 rpm for thirty to sixty minutes) or by preliminary filtration through filter paper, or by a combination of both methods Even under favorable circumstances, however, filtration results in a drop in virus titer in most cases

Chemicals have been used to some extent in rendering suspensions bacteria free. Ether is occasionally used, particularly in work with the virus of poliomyelitis,³ which is relatively resistant to the action of this agent. Similarly, Zephiran (a synthetic detergent) has been used for the isolation of bacteriophages⁴ and of the influenza virus⁵

Antibiotics, which are frequently employed in conjunction with chemotherapeutic agents such as the sulfonamides, are particularly useful in the inoculation of embryonated egg Hirst⁶ developed the technic of amniotic inoculation of unfiltered penicillin-treated throat washings from patients with influenza as a means of isolating the specific virus If streptomycin or sulfadiazine is added as well the results are even better, and this method is fully as sensitive as animal inoculation This work has recently been extended to mumps.⁶ Nevertheless, animal inoculation continues to be widely used for the primary isolation of virus agents, whereas the chick embryo plays an important role in the propagation of the virus after its adaptation by animal passage

Once isolated, the virus may be identified by the production of specific pathologic lesions in the experimental animal or by appropriate serologic technics—that is, by complement fixation, virus neutralization, precipitation-flocculation or hemagglutination-inhibition tests with specific antisera These tests are considered below in greater detail

Serologic Diagnosis

Viral infections in man usually stimulate the production of specific antibodies against the invading virus The demonstration of these antibodies by proper serologic technics offers presumptive evidence of past or present infection with the specific agent This evidence is particularly valuable if it can be shown that the antibodies developed during the course of the patient's illness, since such a finding usually offers convincing proof of the causal relation between the clinical disease and the specific virus The basic principle is analogous to that underlying the serologic diagnosis of bacterial infections For both groups of diseases it is frequently impractical to isolate and identify the causative agent, and recourse must be had to diagnosis by the indirect means of demonstrating the appearance or rise in titer of specific antibodies during the course of the infection This is particularly true in cases of viral infections of the central nervous system, as recently emphasized by Rivers,⁷ who points out the difficulty of isolating the causative agent from the blood or spinal fluid

As in diseases of bacterial origin, the results obtained from the examination of a single specimen of serum in any given case rarely permit a final diagnosis The demonstration of a significant antibody titer against a specific virus in a single serum specimen simply means that the patient has at some time been infected with that particular agent There is no assurance that the present illness is causally connected with the occurrence of these particular antibodies, since clinical or subclinical infection in the past may well have been the specific stimulation for their production In certain cases,—for example, in mumps,—however, when a high titer of antibody such as is characteristic of persons who have recently recovered from the specific disease is found in a single specimen, it may be regarded as highly suggestive or presumptive evidence of the nature of the infection, although an increase in titer cannot be demonstrated But, as in bacterial infections, to obtain a conclusive serologic diagnosis it is always necessary to demonstrate a significant rise in antibody titer during the course of the disease Thus, at least two specimens of serum should be examined one drawn as soon as possible after the onset of clinical signs and symptoms and the other approximately two or three weeks later Usually, this interval between the drawing of specimens during the acute and convalescent phases is long enough to permit a significant rise in antibody titer to be detected The most important exception is in the demonstration of neutralizing antibodies, these frequently appear later than the others, and if this technic is to be applied a third specimen of serum should be drawn six to eight weeks after the onset of the disease.

Table 1 presents the frequent combinations of reactions with serums drawn during the acute and convalescent phases and the conclusions that one is justified in drawing from them

Serologic reactions for the identification of virus agents present particular technical difficulties in the preparation of the antigens. Since viruses cannot be propagated in the absence of living cells, the preparation of viral antigens free from troublesome tissue components is usually difficult and sometimes impossible. The viral antigen usually consists of an extract of parasitized cells. In setting up a test it is

ability to neutralize the disease-producing qualities of the specific virus, as evidenced by the inability of the serum-virus mixture to cause recognizable disease when inoculated into susceptible animals. They are associated with the globulin fraction of serum, the role of complement in this reaction remains uncertain. Mice are the test animals generally used. Although the results of the test on a single specimen of serum occasionally yield presumptive evidence that the disease in question is due to specific virus, it is usually necessary to demonstrate a rise in the neutralizing antibody titer before

TABLE 1 *Combinations of Reactions, with Their Interpretations*

COMBINATION	SERUM DRAWN DURING ACUTE PHASE	SERUM DRAWN DURING CONVALESCENT PHASE	CONCLUSION
1	Negative	Negative	Disease not due to virus tested
2	Negative	Positive	Disease presumably due to virus tested
3	Positive	Positive (significant rise in titer)	Disease presumably due to virus tested
4	Positive	Positive (no significant rise in titer)	1 — contact with the virus tested sometime in past, with no relation to present illness, 2 — first serum drawn too late in course of disease, 3 — second serum drawn too early in course of the disease
5	Not tested	Negative	Disease not due to virus tested
6	Not tested	Positive	Interpretation impossible, unless titer of second specimen is at least as high as that usually found in persons recently recovered from the disease in question, in such cases a presumptive serologic diagnosis may be made on the basis of these suggestive findings.

necessary to include a control consisting of an extract of normal tissue prepared in exactly the same way. If a viral antiserum — prepared by the injection of a suitable animal with tissue cells containing the virus — is employed, the viral antigen used in the actual test should be prepared from infected heterologous cells if possible. These technical difficulties render the serologic diagnosis of viral diseases more complicated and protracted than the process of applying the analogous tests to diseases of bacterial origin.

Four general types of serologic reactions are used for the practical diagnosis of viral infections: virus neutralization, complement fixation, agglutination or flocculation, or both, and hemagglutination-inhibition. The first two find wide application in a variety of diseases, but they are relatively expensive and require time. The third, which can be applied only to the largest virus agents, is limited to variola-vaccinia for all practical purposes. At present the fourth is applicable to influenza and perhaps to mumps, the speed and ease with which it can be carried out, however, give it a distinct technical advantage over the others.

Neutralization tests. Many viral infections stimulate the production of neutralizing antibodies on the part of the host during the course of the illness. These antibodies acquired their name from their

definite diagnosis can be made. Thus, the test must be run simultaneously on two specimens of serum: one drawn as soon as possible after the onset of the illness, and the other drawn four to six weeks later.

The test is usually carried out with a constant amount of virus and varying dilutions of serum, although the reverse — serial dilutions of virus mixed with a constant amount of serum — may be employed, and is particularly useful in the study of neurotropic viruses. Serial dilutions of the serums from the acute and convalescent phases are set up in parallel, and a constant amount of virus is added to each tube. After the incubation of the virus-serum mixtures, susceptible animals are inoculated with samples from each and carefully followed for the development of the experimental disease. In a positive test serum drawn from the convalescent phase shows a significantly enhanced neutralizing or protective effect as compared to that of the acute phase.

This test has been particularly useful in the diagnosis of diseases of the central nervous system due to neurotropic viruses (lymphocytic chorio-meningitis⁸ and the various encephalitides⁹⁻¹²). With the exception of poliomyelitis the test animal generally employed is the mouse, and the route of inoculation intracerebral, or occasionally intraperitoneal. Survival of a significant number of mice injected with a

serum-virus mixture is evidence of the presence of neutralizing antibodies, since the amount of virus in the mixture is such that if injected alone it would result in the death of all the mice. In poliomyelitis the monkey has been used as the test animal,¹⁴ but the multiplicity of the virus strains that cross react weakly if at all render this test impractical for routine diagnostic work.

This test is often applied in the diagnosis of viral infections caused by agents other than the strictly neurotropic ones. Theiler's¹⁵ discovery that mice are susceptible to the intracerebral inoculation of the virus of yellow fever led to Sawyer's¹⁶ application of the neutralization test in survey work. In influenza the virus-serum mixture is inoculated intranasally into a lightly anesthetized mouse.¹⁷ At the end of seven days surviving mice are sacrificed and autopsied, and the lungs are examined for evidence of pulmonary consolidation. The neutralizing antibody content of antivaccinal¹⁸ and ant herpes¹⁹ sera can be estimated by the inoculation of suitable mixtures of virus and immune serum on to the chorioallantoic membrane of the developing chick embryo and by the observation of the reduction in pox produced as compared to the number that develop after the inoculation of similar mixtures of virus and normal serum.

Complement-fixation tests The viral agents causing infectious disease in man generally possess the property of stimulating the production of specific complement-fixing antibodies in the host as a sequel to infection. As such, the formation of these antibodies is entirely analogous to what happens in the course of infectious disease due to bacterial or protozoal agents, and the principles of the methods used for the detection of these antibodies are entirely similar. To establish an unequivocal diagnosis it is essential to prove that antibodies appear or show a significant rise in titer during the course of the infection. Hence at least two specimens of serum from each patient must be examined, one taken as soon as possible after onset, and the other drawn some days later. Since in some diseases the antibody response may occur as early as five days or as late as five weeks after onset, it may be necessary to test three specimens — during the acute phase, one or two weeks after onset and five or six weeks after onset. In a disease such as influenza A or B in which the antibody response is prompt (frequently within a week) and regular the first two specimens usually suffice.

The antigens employed represent the virus agents or their products. The source is frequently infected animal tissue: monkey parotid gland in mumps,²⁰⁻²² mouse brain²⁴ or guinea-pig spleen in lymphocytic choriomeningitis,²³ mouse brain in the various encephalitis,²⁴ mouse lung in influenza,²⁵⁻²⁶ yolk sac in lymphogranuloma venereum²¹ and pitta-cois,²⁷ amniotic membrane in mumps²³ and allantoic fluid in influenza.²⁴ In at least three diseases —

lymphocytic choriomeningitis,²³ influenza²⁴ and vaccinia²⁸ — soluble antigens capable of fixing complement in the presence of the specific antibodies have been isolated from infected tissues.

It has been pointed out that since viruses cannot be cultivated on lifeless mediums, infected tissues or body fluids must be depended on as sources of antigen. In certain diseases — notably in poliomyelitis — the virus is present in the infected tissue in such a low concentration that it has so far been impossible to obtain a complement-fixing antigen from them. In others it has proved difficult to obtain antigen suspensions that are devoid of significant anticomplementary activity. This drawback is particularly serious in cases in which the concentration of the virus in the tissues is low and the corresponding antigen relatively weak in complement-fixing ability. Under these conditions any anticomplementary activity renders the interpretation of the test difficult at best, and special techniques have been evolved to surmount this difficulty.

Again, since the source of antigen is infected tissue or fluid, it is necessary to include in each test an additional control consisting of normal tissue or fluid prepared in exactly the same way to rule out misleading nonspecific reactions. Parenthetically, it should be pointed out that in the identification of an unknown virus by serologic means a similar control must be included — that is, if the immune serum was obtained from a rabbit, the virus agent must be tested against normal rabbit serum as well.

Agglutination and flocculation tests Diagnostic tests employed in agglutination or flocculation techniques are little used in the study of virus diseases with the exception of smallpox. During the course of this disease the patient develops antibodies that agglutinate suspensions of vaccinal elementary bodies.²⁹ Conversely, if a suspension of ground-up variolous crusts is mixed with antivaccinal rabbit serum, flocculation occurs and thus furnishes a practical method for the diagnosis of doubtful cases of smallpox.³⁰⁻³²

Hemagglutinin-inhibition tests The virus agents of certain diseases, notably influenza,³³ mumps³⁴ and vaccinia,³⁵ have the property of agglutinating the red cells of certain avian and mammalian species to a varying degree. Fowl erythrocytes are most widely used, but in some cases human Type "O" cells or guinea-pig erythrocytes may be substituted. This phenomenon furnishes a convenient method of titrating virus activity, and as such is widely employed in many laboratories, particularly in those in which influenza studies are being carried out. Analogous to what happens in neutralizing or complement-fixing antibodies, the patient with influenza develops antibodies that inhibit the ability of the virus to agglutinate fowl or human erythrocytes. After the hemagglutinating activity of the virus agent has been determined, four minimal

agglutinating doses of the virus are added to increasing dilutions of the serum to be tested, and fowl or other mammalian erythrocytes are added. In this manner the ability of two or more specimens of serum from a suspected case to inhibit hemagglutination may be compared. A significant rise in titer permits one to make a diagnosis of the disease. Here again the finding of inhibitory antibodies in a single specimen of serum gives only the limited information that at some time in the past the patient has been in contact with specific virus, either through clinical or subclinical illness or through vaccination. The finding of a high titer of antibodies against influenza A or B in a group of 10 to 20 persons recently recovered from an epidemic respiratory disease, however, strongly suggests that the outbreak was due to the specific virus. Since the test will distinguish between influenza A and B, it is a valuable tool in the hands of the epidemiologist for identifying the causative agent of an outbreak of influenza.

As has been pointed out, the mumps virus and the vaccinia virus also possess the ability to agglutinate erythrocytes of various mammalian species, and it is possible that the hemagglutination-inhibition reaction will be developed as a helpful diagnostic tool for some cases of the former disease at least.

Pathology

Most virus agents show predilections for certain types of tissue, and by virtue of these special affinities they are frequently classified as neurotropic (rabies, lymphocytic choriomeningitis, poliomyelitis and the various encephalitides), dermatropic (herpes, variola, varicella, vaccinia and the other human and animal poxes), viscerotropic (yellow fever and mumps) or respiratory (influenza A and B and psittacosis). It is not surprising, therefore, that some virus agents may be identified by the typical pathologic lesions that they produce. Furthermore, certain viruses cause characteristic intranuclear or intracytoplasmic structures, called "inclusion bodies," within the cells that they parasitize, which are quite pathognomonic of the causative agent. The best known of these is the intracytoplasmic Negri body,⁴³ which is pathognomonic for rabies, but many other virus agents produce analogous bodies, such as the Guarnieri bodies⁴⁴ of vaccinia and variola (intracytoplasmic) and the intranuclear inclusion bodies characterizing the lesions of herpes febrilis,⁴⁵ herpes zoster⁴⁶ and varicella.⁴⁶ These inclusion bodies have their chief diagnostic value in the examination of material obtained at autopsy—for example, the finding of typical Negri bodies in the nerve cells of the hippocampus of man or dog is pathognomonic of rabies and, in a dog that has bitten a human being, is a definite indication for the administration of rabies vaccine to the latter.

Skin Tests

In at least four diseases of viral origin (lymphogranuloma venereum, mumps, vaccinia and influenza), it is possible to demonstrate the development of altered skin sensitivity to the virus agent—or some product of it. In the first disease the Frei test consists in the injection of pus from a bubo,⁴⁷ of infected mouse-brain suspension⁴⁸ or of yolk sac material from infected chick embryo.⁴¹ A positive test is evidenced by the development of an infiltrated inflammatory area with a small, well defined papula. In the Enders test for mumps the material used is a suspension of infected monkey parotid gland²² or infected material from the chick embryo.^{49, 50} As in lymphogranuloma inguinale the reaction reaches its height in forty-eight hours, under proper conditions it fails to show definite necrosis. Since a positive reaction may be due to past as well as present infection, a diagnosis of existing clinical disease cannot be made on the results of the test alone but must be interpreted in the light of the clinical picture. The skin-test materials employed in both these diseases are antigenic and stimulate the production of antibodies that may confuse the serologic picture by causing falsely positive reactions. Hence it is important to complete the serologic diagnostic tests before the patient is tested for dermal hypersensitivity.

It has been shown that infection with influenza A or B viruses results in the development of dermal hypersensitivity to the specific virus or some product of it.⁵¹ As yet no practical use has been made of this test for routine diagnostic work. The so-called "immune reaction" to vaccination with cowpox virus,⁵² which occurs in persons who have suffered from smallpox or who have previously been vaccinated, is another example of dermal allergy resulting from infection with a virus agent.

COLLECTION OF MATERIAL

A large number of specimens received by any laboratory doing diagnostic work are apt to be unsatisfactory for testing for the possible presence of viruses because of the failure to realize that these agents are delicate organisms that quickly die out except under special conditions. Similarly, many serologic specimens sent in arrive contaminated or hemolyzed, or both, their value being thereby appreciably decreased. The proper collection and shipping of these materials is essential. An appreciation of some of the more important of these points will permit the laboratory to render far more assistance to the physician.

Specimens for the Isolation of Virus Agent

These usually consist of blood, spinal fluid, pharyngeal or nasopharyngeal washings or tissue. Unless the specimens can be brought to the laboratory within a matter of minutes special treat-

ment to ensure the viability of the suspected virus agent is necessary. Freezing is the easiest and generally the most practicable method of preserving these agents, and the use of dry ice (solid carbon dioxide) facilitates this process. Blood in amounts of at least 10 to 15 cc should be withdrawn with a dry, sterile syringe and placed in the refrigerator. As soon as clotting has taken place the specimen should be centrifuged, and the serum withdrawn aseptically and stored in sterile pyrex Wassermann tubes or vaccine bottles. The pyrex tubes should be sealed with an oxygen flame, and the bottles with rubber stoppers and pull-on aprons. Spinal fluid should be obtained with sterile precautions and similarly stored. For throat and nasopharyngeal washings it is customary to use nutrient broth or buffered isotonic sodium chloride, sometimes fortified with 10 per cent normal rabbit serum. These washings may be spun slowly for a few minutes to throw down the grosser particles, and the supernatant drawn off and stored in proper tubes or vials.

Freezing the contents of the bottles and vials is accomplished by immersing the tubes or vials in a mixture of alcohol and dry ice and rotating them during freezing to reduce the chance of breaking due to expansion of the fluid. The tubes or vials should be carefully wrapped in cotton wool and paper to prevent breakage and packed in a vacuum bottle surrounded by pieces of dry ice. If the tubes or vials are not properly wrapped they are apt to be cracked in transit. Enough dry ice must be put in to keep the material frozen during the period of shipping to the laboratory, which should be reduced to a minimum.

Samples of tissue submitted for virus studies should preferably be placed in wide-mouthed sterile bottles sealed with a rubber stopper held in place by adhesive tape. The material may then be frozen as outlined above and shipped to the laboratory packed in dry ice. Tight stoppering of the tube or bottle is necessary to prevent the ingress of carbon dioxide, since the acid reaction produced by this gas may inactivate the virus agent. If this is not possible, the second method of choice is to ship the tissue blocks in sterile containers filled with sterile 50 per cent neutral glycerol to a level where the tissue is completely submerged. If the possibility of delay in shipping the specimen exists and it is not feasible to maintain the supply of dry ice in the vacuum bottle the second method is the one of choice.

Although it is possible to preserve virus agents in the dried state by the use of the lyophilization apparatus, such a procedure is rarely necessary or practical under the conditions governing the clinician.

Specimens for Serologic Tests

Specimens of blood for neutralization, complement-fixation, flocculation and hemagglutination-

inhibition tests should not be frozen. A generous sample of blood (at least 15 cc, if possible), should be withdrawn under sterile conditions, a dry syringe being used. After clotting and centrifugation the serum should be removed aseptically and shipped in a suitable sterile rubber-stoppered tube. It is best to store the specimen from the acute phase in the refrigerator at 4°C until the sample from the convalescent phase is obtained. Both tubes should then be shipped together. Although refrigeration in transit is not necessary the specimens should be protected if possible from high temperatures and should be shipped to the laboratory by the most expeditious route.

All specimens should be suitably labeled so as to ensure their proper identification, and a brief abstract of the clinical history should accompany them.

CASE 33421

PRESENTATION OF CASE

First admission A sixty-three-year-old typewriter mechanic entered the hospital complaining of shortness of breath.

He had been in good health until three years before admission, when he developed a cold with considerable cough productive of heavy brownish sputum. He was placed on digitalis and bed rest for eight weeks. He returned to work and had no further difficulty for two years except for shortness of breath on climbing stairs. During the year prior to entry he had several attacks of nocturnal dyspnea with cyanosis. There had been no pain in the chest or swelling of the ankles. A heart murmur had been discovered at the age of twenty years during an ex-

amination for life insurance. Twenty years later, the patient had a severe attack of arthritis involving the shoulders most severely. There had been no arthritis or rheumatism before or after this episode. At the age of forty-seven years an elevated blood pressure was noted for the first time.

Physical examination revealed a well developed and well nourished man in mild respiratory distress with rapid respirations. The fundi showed slight arteriovenous nicking. The heart was enlarged on percussion. The rhythm was grossly irregular. Basal systolic and diastolic murmurs were heard. A high-pitched to-and-fro sound was noted at the apex and over the aortic area. Crackling rales were present at both bases. The liver was palpable three fingerbreadths below the costal margin.

The temperature was 97°F, the pulse 72, and the blood pressure 170 systolic, 94 diastolic.

Examination of the blood revealed a hemoglobin of 12.2 gm and a white-cell count of 11,300, with 83 per cent neutrophils. The nonprotein nitrogen was 29 mg per 100 cc. The urine had a specific gravity of 1.019 and gave a + test for albumin and a 0 test for sugar.

X-ray examination of the chest showed the heart to be generally enlarged, measuring 18 cm in total diameter (internal chest diameter, 31.2 cm). A film taken in the right oblique position disclosed a localized enlargement of the left auricle and the left ventricle displacing the esophagus posteriorly. The hilar shadows were prominent, with increased

vascular shadows throughout both lung fields. A small quantity of fluid was thought to be present in the left pleural cavity. Under fluoroscopy it was noted that the ventricular pulsations were totally irregular in rate, rhythm and amplitude.

The patient was placed on a low-sodium diet and given digitalis, ammonium chloride and Mercupurin, he quickly improved except for intermittent Cheyne-Stokes respirations. By the time of discharge two weeks later he had lost 10 pounds, and the respiratory symptoms had subsided completely.

Final admission (six months later). At home the patient did well for three months on a low-sodium diet with ammonium chloride and digitalis. He then noted the onset of polyuria and polydipsia and lost 12 pounds over a three-week period despite an adequate intake. Examination of the urine revealed a brick-red sugar test. The blood sugar was 441 mg per 100 cc. The patient was given 20 units of protamine-zinc insulin daily and was well controlled thereafter, with blue and occasional green tests. During the six weeks before admission the attacks of breathlessness returned. These were at first relieved by the administration of a mercurial diuretic. Finally, a dry, persistent cough and a return of Cheyne-Stokes respirations were noted. In addition, the patient complained of a plugged sensation in both ears and a feeling of fullness in the epigastrium.

On admission the patient was severely orthopneic. The neck veins were distended in the sitting position. The left border of cardiac dullness was 11 cm from the midsternal line. The rhythm was absolutely irregular, with a rate of 90. Grade III aortic systolic and diastolic murmurs were heard, as well as a Grade II apical systolic murmur. An easily heard apical diastolic rumble was noted. Moist rales were present in both lung fields to the level of the scapula on the right and higher on the left. The liver edge was palpable and slightly tender three or four finger-breadths below the costal margin. There was minimal pitting edema of the ankles.

The temperature was 98.8°F, and the blood pressure 178 systolic, 100 diastolic.

Examination of the blood disclosed a hemoglobin of 11.4 gm and a white-cell count of 12,400, with 84 per cent neutrophils. The fasting blood sugar was 84 mg, and the nonprotein nitrogen 45 mg per 100 cc. The urine had a specific gravity of 1.018 and gave a ++ test for albumin and a 0 test for sugar. The sediment contained 1 red cell and 3 white cells per high-power field.

There was no appreciable change in the x-ray appearance of the chest since the previous examination.

The patient was given 0.2 mg of Purodigin daily. On the day following admission 1 cc of Mercuhydrin was given. The urinary output for the next twenty-four hours, however, was only 640 cc. The dyspnea continued. Mercuhydrin injection was repeated, with no diuretic response.

On the seventh hospital day the patient complained of a steady pain in the right lower quadrant with local tenderness. The liver was no more enlarged or tender than on admission. On the same day he was found to be more severely dyspneic, with respirations of 40 to 50 per minute. He was considerably improved with oxygen, morphine and aminophylline. Examination of the legs at that time was negative.

During the next few days the patient became extremely lethargic. The nonprotein nitrogen rose to 110 mg per 100 cc. The urinary output varied between 500 and 1000 cc daily. The breath became frankly uremic. The abdomen was distended, tympanitic and soft. Fluid intake was increased to 3030 cc on the thirteenth hospital day, with an output of 1140 cc. Urinalysis showed specific gravities of 1.016 to 1.020, + to ++ tests for albumin and a 0 test for sugar. The sediment showed up to 5 red cells and 20 white cells per high-power field. Although the nonprotein nitrogen level dropped temporarily, the clinical appearance remained unchanged. On the fifteenth hospital day a leathery pleural friction rub was noted along the right heart border. During the following week the friction rub grew more widespread, being heard in the right anterior portion of the chest and in the axilla. There were flatness and diminished breath sounds in the right lower portion of the chest posteriorly. Occasionally small amounts of rusty sputum were raised. A chest film showed a small amount of fluid on the right, with areas of atelectasis in the right lower lobe decreasing the size. His condition grew gradually worse, and he expired on the twenty-sixth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. CONGER WILLIAMS. This sixty-three-year-old man died a year and a half after the onset of the cardiac symptoms. He apparently died in cardio-renal failure and possibly with complications in addition to uremia, such as pulmonary infection or infarction and even renal infarction, but I think that it is important at this point to decide what was the underlying lesion in the heart.

First of all, I considered the possibility of rheumatic heart disease, in spite of the patient's age. It is not unusual for a man with rheumatic heart disease to survive to the age of sixty and beyond. We know that at twenty years of age he was turned down for life insurance because of the discovery of cardiac murmurs. This may have been significant, at least, it is suggestive. At the age of forty-seven there was some evidence of arthritis. The episode is not described in detail, but it may have represented an exacerbation of rheumatic fever. Another point in keeping with rheumatic heart disease is the description of the murmurs. I take it, from what I read of the murmurs, that the patient had aortic stenosis and regurgitation. But he might have had

mitral stenosis as well, although the diastolic rumble was not heard at the time of the first admission. This does not mean that it was not present. There may have been other factors, such as congestive heart failure, that made it difficult to hear the murmur at that time. Another finding that is at least consistent with mitral stenosis, although not diagnostic, is auricular fibrillation. With the onset of auricular fibrillation, the character of a mitral diastolic murmur will change, as a result of disappearance of the presystolic crescendo, leaving a mid-diastolic rumble, such as that described at the time of the second admission. A diastolic rumble, however, is also found in dilatation of the left ventricle without mitral stenosis. So far, I can see nothing that makes me rule out rheumatic heart disease with or without mitral stenosis to explain these findings.

Next, the possibility of syphilis must be considered. The murmur of syphilitic aortic regurgitation is often a to-and-fro murmur, with a fairly loud systolic component. But again, in the case under discussion, the diagnosis of syphilis can only be mentioned. We are given no information about the blood Wassermann or Hinton reaction, nor do we know anything about a past history of syphilis. Certainly, the description of the aortic murmurs is compatible with that of syphilitic aortitis. It is possible that this patient had a combination of syphilitic aortitis and something else. We know that he had hypertension, but I suspect that it played an unimportant role, at least in the heart disease.

Calcereous aortic stenosis is possible but is usually not associated with a diastolic blow. There is a school of thought that holds that calcareous aortic-valve disease is always on a rheumatic basis. That is not a point to be settled now.

Another possible cause of the presence of auricular fibrillation is chronic coronary heart disease. At this age the complication of auricular fibrillation without other heart disease to explain it is fairly common. I doubt that there was previous myocardial infarction, although there is no report of an electrocardiogram.

The possible causes of the terminal uremia should next be considered. Nephrosclerosis is perhaps the most probable cause in this situation. We should think of the possibility of mercurial poisoning because of the fact that the urinary output decreased after two mercurial diuretics. The toxicity of these compounds is increased in connection with a low urinary output following their administration. Although toxic mercurial nephrosis as a result of these diuretic compounds is rather unusual, there have been 2 reported cases. In one described here in conference a year and a half ago, there was a reasonable assumption that the final uremia was based on the use of mercurial diuretics.*

Another condition that seems to recur quite often in these conferences is that of primary glomerulonephritis, even in older patients. We have no right to make that diagnosis but only to suggest it.

Renal infarction in a patient with auricular fibrillation has already been mentioned. The patient in the case under discussion had uremia resulting from painless renal infarction without hematuria.

I should like to mention another possibility of renal disease—that is, intercapillary glomerulosclerosis. We know that the patient had diabetes and we also know that he had had albumin in the urine for some time before death.

On the basis of these findings, therefore, I favor a diagnosis of rheumatic heart disease with aortic stenosis and regurgitation, mitral stenosis, auricular fibrillation, cardiac enlargement and congestive heart failure complicated by terminal uremia on the basis of nephrosclerosis and, possibly, a pulmonary infection or infarction in addition.

DR EDWARD F. BLAND: Needless to say, this case was somewhat of a puzzle. To take the lesser problem first, the patient developed acute diabetes under our observation during the last two or three months. He had severe, extensive valvular heart disease. We thought that it was rheumatic with a hypertensive element, involving principally the aortic valve with stenosis and regurgitation, and like Dr. Williams, we were uncertain whether there was mitral disease in addition. Temporarily, he did well on a low-sodium regime. In fact, we were able to discontinue mercurial diuretics for some months prior to the terminal failure. Then, abruptly, he became worse and failed to respond to mercurial diuretics or anything else, with increasing evidence of uremia. We thought that there was infection or infarction somewhere in the body. We could not make a diagnosis of bacterial endocarditis. The cultures were negative, and it did not look like that. We were uncertain about possible rheumatic infection. He was slightly jaundiced,—that does not appear in the record,—but the van den Bergh reaction was 5 mg per 100 cc, as I recall, which made us suspect more strongly infarction somewhere in the body. We wondered about terminal nephritis or terminal infection in the genitourinary tract, but we were unable to prove either. The patient failed to respond, and died in uremia.

DR WILLIAMS: You did not think at the first admission that the to-and-fro sound described was a friction rub and that he had acute rheumatic myocarditis?

DR BLAND: That was on the original admission. The terminal friction rub was of some interest. It was over the whole right lung, and of such intensity that it was easily palpable.

CLINICAL DIAGNOSES

Rheumatic and hypertensive heart disease, with aortic regurgitation

*Case records of the Massachusetts General Hospital (Case 3145). *New Eng J Med* 233:567-570, 1945

Auricular fibrillation and congestive failure
 Pulmonary infarct
 Uremia
 Nephritis?

DR WILLIAMS'S DIAGNOSES

Rheumatic heart disease, with aortic stenosis and regurgitation
 Mitral stenosis?
 Cardiac enlargement.
 Congestive heart failure
 Auricular fibrillation
 Nephrosclerosis
 Uremia
 Pulmonary infarction?

ANATOMICAL DIAGNOSES

Calcareous aortic stenosis
 Hypertrophy and dilatation of heart
 Thrombosis of right and left auricular appendages
 Pulmonary emboli and infarction
 Renal emboli multiple, with infarction

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY Post-mortem examination showed massive renal infarcts. The right kidney, the side where the pain was, had multiple infarcts, which occupied two thirds of the cortex. The left kidney was enlarged and also showed a single infarct. The source of these emboli was, with little doubt, a thrombus in the left auricle. The auricular appendage was still massively filled with thrombus at the time of autopsy. There was also a large thrombus, and the right auricular appendage, which had been the source of pulmonary emboli, and the right lower lobe of the lung were almost completely involved by three separate infarcts that were nearly contiguous. Also, two infarcts were present in the left lower lobe. The valvular disease of the heart consisted of calcareous aortic stenosis with marked interadherence of the commissures. There is nothing that would allow one to be dogmatic regarding whether or not this developed on the basis of a congenital bicuspid valve, but the mitral valve was completely normal. There were no rheumatic stigmas in the myocardium. The friction rub was obviously due to pleuritis, secondary to the pulmonary infarction. There was a fibrinous exudate, 3 mm thick, over the involved area.

DR. BLAND Before we close, would you be willing to discuss the infrequency of hematuria in massive or extensive renal infarction?

DR. MALLORY I was wondering if anyone would comment because this case and the other case discussed today* had massive renal infarction, but only occasional red cells were found in the urinary sediment.

DR. BLAND We looked repeatedly for hematuria, but at no time were there more than a few red cells in the sediment.

CASE 33422

PRESENTATION OF CASE

A seven-year-old boy was admitted to the hospital with extreme dyspnea.

About five weeks prior to admission the child began to complain of dyspnea on exertion. Ten days later vomiting, diarrhea and pain in the right upper quadrant developed, and he began to have rapid, grunting respirations. He was admitted to another hospital, where examination revealed myocardial enlargement in all diameters, with a faint systolic murmur at the apex and an enlarged tender liver. The blood pressure was 80 systolic, 60 diastolic. During the hospital stay the temperature remained normal, and the sedimentation rate was not elevated. An electrocardiogram showed marked left-axis deviation, with a slightly prolonged PR interval. Digitalis was administered, with no appreciable effect. The patient was also given mercurial diuretics, with a good output following the first two doses, but no increase was subsequently noted. After about three weeks of hospitalization, with a steady downhill course, he was admitted to this hospital.

There was a history of partial deafness since birth, aggravated by an attack of whooping cough at the age of four years, and also of subsistence on a diet composed largely of "Coca-Cola," "soda" and pastry for several months.

Physical examination disclosed a poorly nourished, cyanotic boy, who was gasping for breath and partially disoriented. The cardiac impulse was in the sixth left interspace in the anterior axillary line. The heart sounds were of poor quality, and a gallop rhythm was present. A pericardial friction rub was heard at the apex. There were a few moist rales at both bases posteriorly, and a questionable pleural friction rub was heard. The liver edge was palpated 4 cm. below the right costal margin, and was tender.

The temperature was 95°F, the pulse 120, and the respirations 60. The blood pressure was unobtainable.

Examination of the blood revealed a red-cell count of 4,680,000 and a white-cell count of 4800, with 88 per cent neutrophils. The urine had a specific gravity of 1.020 and contained a moderate trace of albumin, and many casts were observed in the sediment. An electrocardiogram showed a rate of 150, with a PR interval of 0.14 second and some evidence of intraventricular block.

Cedilamid (0.4 mg.) and fluids were administered intravenously. The patient followed a rapid downhill course and died about eight hours after admission.

DIFFERENTIAL DIAGNOSIS

DR. GERTRUD E. REYERSBACH This is a history of myocarditis and congestive failure, and the prob-

*Case records of the Massachusetts General Hospital (Case 33311) *New Eng J Med* 237:163-167, 1947.

lem is to decide what type of myocardial disease this child had

The most frequent cause of myocarditis in childhood is rheumatic fever. In most cases myocardial involvement in rheumatic fever is accompanied by fever. Severe myocardial disease without involvement of the endocardium, — that is, without valvular lesions, is rare. The patient is reported to have had a faint systolic apical murmur. This description does not fit too well with valvular disease, but the murmur may have been due to cardiac dilatation and a relative mitral insufficiency.

The prolonged PR interval — we do not know how much prolonged — is consistent not only with a diagnosis of rheumatic carditis but also with some other forms of carditis. We do not know whether the electrocardiogram was taken before digitalis was administered. A normal sedimentation rate in the presence of congestive failure is frequent in rheumatic carditis. Failure to respond to digitalis is not rare, but in this case it may have been due to the fact that inadequate doses of digitalis were administered.

The absence of any other signs of rheumatic fever, such as joint pains, nodules, rashes and epistaxis, makes the diagnosis of rheumatic myocarditis unlikely.

We then come to a second group of diseases that may cause myocarditis in this age group — namely, infection. There is no indication that this boy had such a disease as typhoid fever or that he had a septicemia. Diphtheria is known to cause severe myocarditis. No mention is made of a sore throat or a skin lesion that might have been of diphtheritic origin. A prolonged PR interval, intraventricular block and low blood pressure are often seen in diphtheritic myocarditis, but cardiac dilatation is comparatively rare. Furthermore, one would have expected the boy to succumb earlier had he had diphtheritic myocarditis.

Nothing in the history suggests hyperthyroidism or hypothyroidism, nor is there any mention of the ingestion of such poisons as phosphorus, arsenic and chloroform.

We know that myocarditis occurs in acute hemorrhagic nephritis. I think that we can safely discard this diagnosis without further discussion. Also, the diagnosis of chronic nephritis with cardiac failure can be eliminated. True, a urine examination showed albumin and casts, but these findings are not uncommon in congestive failure. I doubt that they were due to mercury poisoning.

It is said that the patient had subsisted on a diet comprised largely of Coca-Cola, soda and pastry for a few months before becoming sick. This indicates that the diet was poor in thiamine. Did the patient have beriberi? We are not told whether any signs of polyneuritis were found or whether the deep reflexes were diminished. A serum protein

determination is not recorded. In beriberi, the blood pressure is usually low, as in this patient. The heart is greatly enlarged, often generally, sometimes the right side more so than the left. The electrocardiogram usually shows low voltage of QRS segments and T waves. A diagnosis can only be made by clinical observation, careful appraisal of the diet and sometimes a clinical trial with thiamine.

Two rare congenital lesions that produce cardiac insufficiency are the cardiac form of glycogen disease and rhabdomyoma of the heart. In both diseases hypertrophic heart-muscle cells containing large vacuolated spaces filled with glycogen are found. Practically all reported cases of rhabdomyoma have been associated with tuberous sclerosis, of which this child showed no signs.

He may have had cardiac glycogen disease, we cannot make the diagnosis positively during life. I do believe that the large liver was not due to glycogen disease but to congestive failure.

Lastly, we come to the group of interstitial myocarditis described by Fiedler.¹ In these cases cardiac enlargement, often with no murmurs, and congestive failure are apparent clinically. These children are usually afebrile and do not respond well to digitalis or diuretics. The disease is more frequently found in smaller children but has been described in a child of the same age as this patient. The clinical picture and course fit well with this disease.

In making a diagnosis, I believe that we must consider seriously three possibilities: beriberi, glycogen disease and interstitial myocarditis. It is unlikely, however, that he had beriberi myocarditis. I am sure that he must have had thiamine before he went on this peculiar diet, and also I should think that he had received thiamine in some form in the other hospital. This type of myocarditis is more frequently seen in infants with a poor dietary history than in older children. I must therefore decide between glycogen disease and interstitial myocarditis, and I shall guess that he had interstitial myocarditis, congestive failure and terminal pericarditis.

DR ALFRED KRANES: Do you think that the electrocardiographic findings are against interstitial myocarditis?

DR REYERSBACH: A little.

CLINICAL DIAGNOSIS

Myocarditis

DR REYERSBACH'S DIAGNOSES

Interstitial myocarditis

Congestive failure

Terminal pericarditis

ANATOMICAL DIAGNOSES

(Beriberi heart disease, probable)

Diffuse fibrosis of myocardium

Hypertrophy and dilatation of heart

Chronic passive congestion

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: Post-mortem examination showed primarily a hypertrophied heart weighing 210 gm. All the chambers were dilated and moderately hypertrophied. The pericardium contained fluid but was clear, and there was no evidence of pericarditis. The valves were entirely normal. The ventricular endocardium seemed slightly thickened. The musculature was not grossly abnormal, but when the microscopical sections came through, they presented a very unusual and interesting appearance. In all of a number of blocks there was diffuse fibrosis, with a moderate degree of edema of the interstitial fibrous tissue. There was no inflammatory infiltration, and there were no areas of necrosis or destruction of the cardiac muscle cells. These cells looked hypertrophied, as one would expect from the increased weight of the heart, and showed mild degenerative changes in which the muscle fibers were widely separated from one another by a homogeneous, slightly hyaline material, which I could not identify. A few cells showed hydropic vacuoles. There was no evidence of glycogen storage.

We are therefore presented with a diffuse fibrosis of the myocardium without evidence of present or past destruction of muscle cells or any traces of inflammation. Most types of myocarditis are associated with extensive destruction of muscle cells—for example, that seen in diphtheria. It is conceivable that an interstitial myocarditis such as is seen following sulfadiazine therapy or in typhus fever can result in fibrosis somewhat similar to what

was observed in this case, but I would expect it to be focal rather than diffuse and there is not the least reason for suspecting such etiologic agents in this patient. On the other hand, this appearance has frequently been described in beriberi.²⁻⁴ Although the histologic picture was not specific, the findings were compatible, and that is my first choice of diagnosis. We found nothing else in the rest of the body that was of any significance, except evidence of congestion and cardiac failure.

DR. ALLAN M. BUTLER: In pediatrics we are often puzzled regarding why we do not see more thiamine deficiency because our infants exist on a diet that is very low in thiamine and often have severe bouts of nutritional disturbance. The diet is sometimes high in sugar, and yet we hardly ever see any objective evidence of thiamine deficiency.

DR. MALLORY: In this part of the world almost the only cases of frank beriberi heart disease are seen in chronic alcoholics.

DR. SEDGWICK MEAD: Were there any changes in the peripheral nervous system?

DR. MALLORY: Unfortunately, they were not studied. There was no clinical evidence of neuritis, however.

groups of private patients, or by surgeons long on speed and short on incisions. But these patients will not drift off into the happy limbo of another man's practice. They have made their prepayments over the years and they will return for amends, the bad news will gather like flies around offal on a hot summer day. The backers of this scheme will come to realize that, although their expenses have been met, they are operating under a deficit — a type of deficit peculiar to medical undertakings.

The definition and control of competence is the central problem of medicine today. It seems wiser to move toward the solution of this problem than to multiply the total number of doctor-patient contacts by legislation.

A FITTING MEMORIAL

THE published notice of the services for the late Dr. Robert N. Nye contained a request that flowers be omitted but that in their stead donations be sent to the Massachusetts Division of the American Cancer Society. The request met with a remarkable response. In scarcely more than two weeks over \$1600 had been received, none of it obtained by solicitation.

There is a growing sentiment that this sum should be expanded into a real memorial fund, in view of the great interest that Dr. Nye had in the American Cancer Society, and the time and effort that he had given to it in addition to his editorial and other duties.

Any persons who are interested in adding to this fund should send their donations, in Dr. Nye's name, to the American Cancer Society (Massachusetts Division) Inc., 476 Boylston Street, Boston 16.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

HAWKINS — Henry Hawkins, M.D., of Belmont, died on September 4. He was in his seventy-fifth year.

Dr. Hawkins received his degree from University of Pennsylvania School of Medicine in 1902. He was ophthalmologist at the Perkins Institute for the Blind and the School for Crippled Children. He was on the staffs of the Boston City, Cambridge City and Cambridge Emergency hospitals and was a consulting surgeon to the Massachusetts General Hospital. He was a member of the New England Ophthalmological Society and a fellow of the American Medical Association.

His widow and two sisters survive.

LUCAS — Julian D. Lucas, M.D., of Brookline, died on June 3. He was in his seventieth year.

Dr. Lucas received his degree from Tufts College Medical School in 1902. He was a former member of the Massachusetts Medical Society.

MURPHY — Harold A. Murphy, M.D., of Jamaica Plain, died on September 23. He was in his fifty-sixth year.

Dr. Murphy received his degree from Tufts College Medical School in 1915.

His widow, a son, two brothers and a sister survive.

APPLICANTS FOR FELLOWSHIP

The following three names were omitted from the list of applicants published in the *Journal* of October 9.

ESSEX NORTH DISTRICT

WEINSTEIN, MAX I., 220 Walnut Street, Lawrence.

Middlesex University School of Medicine, 1936. Sponsor N. F. DeCesare, 57 Jackson Street, Lawrence.

Harold R. Kurth, *Secretary*, 57 Jackson Street, Lawrence.

MIDDLESEX NORTH DISTRICT

PELOQUIN, LAVAL U., 834 Stevens Street, Lowell.

Georgetown University School of Medicine.

Brendan D. Leahy, *Secretary*, 9 Central Street, Lowell.

MIDDLESEX SOUTH DISTRICT

PAGEL, MAX MANFRIED, 21 Clark Street, Newton Centre.

University of Breslau, 1920. Sponsor B. P. Colcock, 78 Hull Street, Newtonville.

Alexander A. Levi, *Secretary*, 481 Beacon Street, Boston.

A HUNDRED YEARS AGO

We have ever found it difficult to impress upon females the importance and absolute necessity of remaining for a sufficient length of time after confinement in a horizontal position, and keeping perfectly quiet. We are satisfied that the practise of getting out of bed too soon after confinement is very general in our community and hence it is that such a very large proportion of our female population suffer with prolapsus and procidentia uteri. Sometimes this is attributable to the want of proper precaution on the part of medical advisers, but more frequently it is owing to the folly of patients themselves. On the third or fourth day after parturition, a patient who is "very smart," feels able to sit up in bed, or in an easy chair, and in spite of all that the physician can say, she will, in his absence, sit up for the purpose of changing her clothes, or get out of bed altogether, that it may be made up, and not infrequently walk across the floor, by way of testing her strength. A moment's reflection must convince any one of the impropriety of such conduct. We are satisfied that if due attention were paid to the proper "getting up" after confinement, we would not see so many young and lovely wives, pale and anaemic, and unable to take the least exercise, or even attend to their ordinary household affairs, without the greatest pain — A quarterly

meeting of the Counsellors of the Massachusetts Medical Society was held at the Masonic Temple a few days ago. There have not been so many Counsellors together at an ordinary business meeting within the compass of our recollection. Everything passed satisfactorily until Dr Childs of Pittsfield resolved that *Whereas*, The great object of medical association is the advancement of medical science, and the promotion of harmony and good feeling in the profession, thereby contributing to the best interests of society, and *Whereas* the present organization of the Massachusetts Medical Society does not fully meet these important objects, therefore, *Resolved*, that a change in the organization of the Massachusetts Medical Society is in our opinion deemed both wise and expedient, and that the change consist in making the basis of the State Society, local or county associations. — The whole number of cases treated by the Physicians of the Boston Dispensary during the year ending Sept 30, was 3290. The number of "Bostonians" in this list is stated in the Abstract of Reports as 163, other Americans, 458, Hibernico-Americans, 657, Irish, 1874. Only 150 of the patients are reported as intemperate. — A great variety of beautiful dental work was on exhibition at the late Quincy Hall fair. By ingenious clock machinery, artificial jaws of porcelain teeth were continually opening and closing, as spectators were passing along. — We are gratified to learn that a Professorship of Insanity has been established at one Medical School. The Willoughby University, Columbus, Ohio, has appointed Samuel M Smith, M.D., Professor of Medical Jurisprudence and Insanity. We think there should be a distinct course of lectures on mental maladies, at every medical school. Dr Smith has some practical knowledge of insanity, having been an Assistant Physician at the Ohio Lunatic Asylum for several years. — Died, in Pembroke, Mass., Dr Anthony Collamore, a worthy physician and an honest man. The disease which occasioned this sad bereavement was dilatation of both auricles, and both ventricles of the heart, without hypertrophy. The pericardium was adherent to the heart, and also the diaphragm and mediastinum. Although confident that disease was praying upon his vitals, yet so slight was the uneasiness occasioned by the inflammation that he was scarce ever detained from attending to the duties of his laborious profession. He had been a practitioner of medicine in Pembroke nearly forty years. He was one of those old-fashioned physicians, who never blazon forth their cures as wonderful. Tender and sympathizing, he softened the pillow of the sick, and dropped a tear with relatives bereaved. Well can it be said, that those who knew him best, deplore him most. — Extracted from the *Boston Medical and Surgical Journal*, October, 1847.

MISCELLANY

ALVARENGA PRIZE

The College of Physicians of Philadelphia awarded the Alvarenga Prize on July 14, 1947, for this year to Dr. Joseph Aronson, of the United States Bureau of Indian Affairs, in recognition of his studies on the evaluation of BCG vaccine in the control of tuberculosis.

The Alvarenga Prize was established by the will of Pedro Francisco daCosta Alvarenga, of Lisbon, Portugal, an associate fellow of the College of Physicians, to be awarded annually by the College of Physicians on each anniversary of the death of the testator, July 14, 1883, for outstanding work.

NOTES

The following Massachusetts physicians were recently appointed fellows in the American College of Surgeons: Thomas W. Botsford, Brookline, Weston T. Buddington, Boston, John H. Crandon, Boston, William H. Creamer, Fall River, William F. Crockery, Brookline, George F. Emerson, Boston, Francis J. Hanley, Brookline, Edward Harding, Brookline, J. Hartwell Harrison, Boston, Herbert E. Hedberg, Worcester, Donald Hight, Worcester, Stanley O. Hoerr, Boston, Elwood O. Horne, Worcester, Chester W. Howe, Framingham, George Kelemen, Boston, Benjamin deF. Lambert, Lowell, Henry C. Lawson, Fall River, Joseph P. Marnane, Gardner, John B. McKittrick, Boston, Carter R. Rowe, Boston, Morgan Sargent, Quincy, S. Peter Sarris, Lynn, John A. Seth, Boston, Artemas J. Stewart, Lowell, William W. Teahan, Holyoke, Robert S. Thomson, Roslindale, Howard M. Trafton, Dorchester, John B. Vernaglia, Medford, Joshua H. Weeks, New Bedford, Charles A. Wheeler, Leominster, and Hilary F. White, Fall River.

NORFOLK MEDICAL NEWS

The *Journal* welcomes the reappearance of the *Norfolk Medical News*, after an interval of two years during which it had suspended publication. Appearing first in 1940 and continuing in regular publication until 1945, the *News* appears now in its sixth volume. Distributed to the entire membership of the parent society, the *News*, offering the use of its pages as a general forum, is more than the journal of a single district.

CORRESPONDENCE

A PERTINENT SUGGESTION

To the Editor: Well trained physicians in the Commonwealth frequently see many patients who have been treated poorly — both professionally and financially — by other less well trained physicians, the majority of whom are graduates of medical schools unapproved by the Council on Medical Education and Hospitals of the American Medical Association. Furthermore, most of the physicians with inferior training take their patients to private hospitals not approved as Grade A by the Council on Medical Education and Hospitals. In these hospitals the standards are frequently poor, and surgical and medical care leave much to be desired.

The same physicians are not allowed to practice in first-rate hospitals. Moreover, until the recent institution by the Massachusetts Medical Society of refresher courses for physicians who are veterans, and for any other physicians who might wish to attend, little or no encouragement has been given physicians to improve their professional status and ability. If poor medicine, shabby ethics, and dangerously inadequate hospital care are to be prevented in the Commonwealth, all poorly trained physicians must be encouraged to improve their knowledge, and they must also be rewarded for such improvement. How can this be brought about?

It is my opinion that the Massachusetts Medical Society can do a great deal by offering prescribed courses to all physicians to be given throughout the year by the three leading medical schools in the Commonwealth. These courses should be for the express purpose of allowing those who pass the final examinations to qualify for admission to the courtesy staffs of Grade A hospitals.

Naturally, physicians passing the prescribed courses would also have to qualify morally and ethically. But that problem would rest with the Grade A hospitals that chose to admit to their staffs the physicians who had passed the required courses.

Now that recent legislation prohibits graduates of non-approved medical schools from obtaining licenses to practice medicine in Massachusetts, we have at last only to contend with all the physicians — graduates of the same unapproved schools — who already hold such licenses. Of course, unless they were strongly urged to do so, there would be many substandard physicians who would not take the required courses, and who therefore might never enjoy the benefits of caring for their patients in Grade A hospitals. There would be a great many other such physicians, however, now legally practicing medicine in the Commonwealth, who would jump at the chance to improve their knowledge and so to be accepted by approved medical institutions.

By the offering of such concrete encouragement and opportunity by the Massachusetts Medical Society many of these well meaning, but unhappily poorly trained physicians, would lose the "chip on their shoulders", they would be in instead of out with the majority of their profession, and at the end of a few years the caliber of medical care in the Commonwealth would be greatly enhanced. The number of second rate and third-rate private hospitals would be reduced materially.

It is hoped that the Society will work toward some such goal as I have outlined above.

J. ROBERT LYMAN, M.D.

24 Forest Street
Wellesley Hills

BOOK REVIEW

Diseases of the Basal Ganglia and Subthalamic Nuclei By D. Denny-Brown, M.D., Ch.C., Dr. Phil., F.R.C.P. 8¹/₂ cloth, 74 pp., with one colored plate. New York: Oxford University Press, 1946. \$2.50. Reprinted from the Oxford Loose-Leaf Medicine.

This short monograph is issued as a reprint from *Oxford Loose-Leaf Medicine*, Volume VI, in a convenient form for those interested in the subject. The contents appear to be unchanged. There are a separate index and an extensive bibliography. One illustration in color is fairly satisfactory. The review, by a well known authority, is an excellent one, and all physicians seeking knowledge of the diseases of the basal ganglia are referred to this work. The chief clinical syndromes covered are paralysis agitans, postencephalic Parkinsonism, hepatolenticular degeneration, dystonia, athetosis and Huntington's and other forms of adult chorea. Each disease is discussed from the point of view of definition, the symptomatology, pathology and treatment. Although the article is brief and intended for reference by the internist or the general practitioner, the quality of the evaluations and the clearness of the presentation make this short monograph an outstanding contribution.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

La Douleur By Dr. Paul Chauchard, directeur adjoint à l'École pratique des hautes Études. 128 pp., 12^o, paper, with ten illustrations. Paris: Presses universitaires de France, 1947. Forms No. 252 of "Que sais-je?" Le point des connaissances actuelles.

This small popular work on pain is divided into three parts: physiology, pathology, including visceral, neuralgic and central-nervous-system pain, and treatment, including medical and surgical treatment and means for alleviating pain. The material is well organized, and the text well written. The catalogue of this popular series shows that the whole field of knowledge is well covered. The series should prove interesting to French-reading persons.

Annual Report of the Baruch Committee on Physical Medicine for the period of April 1, 1945, to December 31, 1946 8 paper, 161 pp. with 35 illustrations. New York The Committee, 1947 Free.

This is a comprehensive report of the activities carried on by thirteen medical schools supported by grants from the Baruch Committee. The total disbursement for the period under consideration was slightly over \$107,369.

The Role of Hormones in Sterility By Bent C. Böving A B 4 paper 38 pp. with one plate (The Schering award for 1946.) Bloomfield New Jersey Schering Corporation Medical Department, 1947 Free.

This essay received first prize in a competition participated in by forty-eight contestants. Mr. Böving is now in the class of 1948 at the Jefferson Medical College. He discusses the various aspects of his subject, especially from the viewpoints of chemistry and physiology.

Copper and Health. Issued by the Copper and Brass Research Association 8^{1/2} paper 47 pp. New York The Association, 1947 Free.

In this pamphlet the various aspects of copper in relation to health are discussed including toxicity value as a nutrient and use in cooking utensils, in water supply systems and in ancient and modern medicine. Much of the information presented in the booklet was compiled by Dr. R. R. Sayers, director of the Bureau of Mines, Department of the Interior when he was serving as chief of the Division of Industrial Hygiene, United States Public Health Service. He was assisted by Sara J. Davenport. The printing is well done with a good type on good paper. This small pamphlet should prove useful for reference purposes in all medical and general libraries.

Röntgen Interpretation By George W. Holmes, M.D., member, Board of Consultation, Massachusetts General Hospital, and clinical professor of roentgenology emeritus Harvard Medical School and Laurence L. Robbins, M.D., radiologist in-chief, Massachusetts General Hospital, and associate in radiology Harvard Medical School. Seventh edition, thoroughly revised 8, cloth, 398 pp. with 266 illustrations. Philadelphia Lea and Febiger, 1947 \$7.00.

This standard textbook has been thoroughly revised to include the advances in the subject since the publication of the previous edition including particularly new material on diagnosis and treatment. The book is well published in every way. It should be in all medical libraries and in the libraries of physicians interested in radiologic diagnosis.

Recent Trends in Alcoholism and in Alcohol Consumption By E. M. Jellinek, Sc.D. director Section of Studies on Alcohol Laboratory of Applied Physiology Yale University 4^{1/2} paper, 42 pp. with four figures and twenty-seven tables. New Haven Hillhouse Press, 1947 50 cents.

This is a statistical study of the apparent consumption of alcoholic beverages for the period 1850 to 1945. The first part analyzes the over all consumption for the United States and the second that by states. Population and consumption of persons over drinking age, which is placed at fifteen years are compared.

Separate tables are given for consumption of distilled spirits (liquor) and wine and for total absolute alcohol contained in liquor, beer and wine. Chronic alcoholism is portrayed in a number of tables. The study was projected for the purpose of ascertaining the truth concerning the prevalent opinion that there has been an increase in drinking and a rise of alcoholism particularly among women. The summary reveals that the per capita consumption of alcoholic beverages by persons of drinking age rose steadily during the course of World War II but remained below the levels of the pre-Prohibition years, and that the rise in consumption between 1940 and 1945, as shown by the tables, "was due to an increase of 35 per cent in the number of consumers, but individual consumption hardly increased at all." Since 1850 the per capita consumption of distilled spirits has decreased by 53 per cent, whereas that of beer has increased by 862 per cent. The estimated number of chronic alcoholics

was greatest in 1910. Between 1915 and 1920 the level dropped sharply and the decrease was maintained during the Prohibition era. Between 1930 and 1945 the rate increased by nearly 28 per cent, but this rate was still 31 per cent below that in 1910.

The rate of female alcoholism was higher in 1910 than in 1945. The drop from 1915 to the Prohibition years was less in the female than in the male rate. Likewise the rise of the female rate between the last Prohibition years and 1945 was only 12.6 per cent as compared with an increase of the male rate of alcoholism of 43.6 per cent. The entire rise in the female rate occurred during the war years. From 1940 to 1945 the female rate increased by 12.6 per cent and the male rate by 22.6 per cent. Dr. Jellinek concludes that there is no basis for the contention that female inebriety is increasing faster than male inebriety. The rate of chronic alcoholism in cities of 100,000 and over is higher by 33.7 per cent than that in smaller cities and higher by 105 per cent than that in rural areas. The entire increase in the rate of chronic alcoholism since 1930 has been in urban areas and the rate in the rural areas has decreased slightly.

There is a great variation in the rate by states owing largely to variation of the Dry sentiment. The statistics show that there was no shift in age at full fledged alcoholism. This comprehensive survey is a valuable document and should be in all medical and reference libraries and in the libraries of persons interested in the subject.

Doctor Don't Let Me Die! By S. S. Keiner M.D. Collaborator, Dan Gordon. With an introduction by Henry E. Sigerist, M.D. 8^{1/2} cloth, 486 pp. Boston Meador Publishing Company 1947 \$3.50.

The author writing in a fictional form has presented his views on the inadequacies of present-day medical practice and favors the passing of the Senate bill providing for a national health program. The book is essentially an autobiography.

Pharmakologie als theoretische Grundlage einer rationalen Pharmakotherapie By H. O. Møller, ord. Professor der Pharmakologie an der Universität Kopenhagen. Übersetzung und Bearbeitung nach der dritten dänischen Auflage von Dr. O. Walker 4^{1/2} cloth, 744 pp. with 34 illustrations. Basel Benno Schwabe and Company 1947 48 Swiss francs. Imported by Grune and Stratton New York N.Y.

This standard Danish work on clinical pharmacology is now available in a German language translation. The subject is treated from the viewpoints of physiology and experimental pharmacology. The author has adopted a simple classification of ten divisions as follows: organic bacterial antiseptics; substances of predominant local action; chemotherapeutics including the coal tars, sulfonamides and antibiotics; narcotics; alkaloids and other substances acting on the autonomic nervous system; cardiovascular drugs; substances predominantly acting on heat regulation and metabolism; vitamins; hormones and related body regulating substances including insulin and cortin; salts, acids, bases; light metals and metalloids and heavy metals.

The material is well organized and the text well written without redundancy. Under each drug there is given the chemical formula and chemistry, pathological actions and therapeutic indications; the official preparations of the German Swiss and other pharmacopoeias are also presented. Selected references of fundamental character are appended to the drugs when considered necessary. In addition there is a forty-seven-page bibliography arranged alphabetically by authors following the text. This bibliography and the references are international in scope embracing all languages and including a good representation of American and English writers. References as late as 1945 are cited. A comprehensive subject index concludes the volume. A valuable index of definitions is printed on page 724. The publishing is excellent in every way. The type is good; the margins wide; the paper soft and the type page pleasing to the eye. Although the book is large, the weight is comparatively light for the size of the volume. It is a pleasure to handle such an excellent volume. This book should be in all medical schools, universities and large medical libraries as well as in all collections pertaining to pharmacology and pharmacy. It is hoped that an English translation will be forthcoming.

Psychopathology A survey of modern approaches By J Ernest Nicole, O B E, L M S S A, D P M R C P & S, medical superintendent, Winwick Mental Hospital Fourth edition 8°, cloth, 268 pp Baltimore Williams and Wilkins Company, 1946 \$4 75

In this new edition few changes have been made in the text, but the bibliography has been brought up to date so far as possible and comprises thirty-one pages made up entirely of monographs and books. The book is well printed with a good type on good paper with prewar margins. This short treatise should prove useful to persons interested in the subject.

A Manual of the Common Contagious Diseases By Philip Moen Stimson, M D, associate professor of clinical pediatrics, Cornell University Medical College, visiting physician, Willard Parker Hospital, director, Poliomyelitis Service, the Knickerbocker Hospital, medical director, The Floating Hospital of St. John's Guild, associate attending pediatrician, the New York Hospital, and consulting pediatrician, the Meadowbrook, Bergen Pines and Norwegian Lutheran hospitals. Fourth edition, thoroughly revised 12°, cloth, 503 pp., with 67 illustrations and 8 plates, 6 in color Philadelphia Lea and Febiger, 1947 \$4 00

A large part of this new edition of a standard, authoritative manual has been rewritten, and much new material added to the text to bring it up to date, including a new chapter on the sulfonamides and the antibiotics. The chapter on poliomyelitis is essentially new. The bibliographies appended to each disease have also been brought up to date. A number of new illustrations have been added to the book. The printing is well done with a good type on good paper with wide margins. The manual should prove useful for quick reference purposes to physicians, nurses and health officers.

Occupational Diseases of the Skin By Louis Schwartz, M D, medical director, United States Public Health Service, chief, Dermatoses Section and associated clinical professor of dermatology and syphilology, New York University College of Medicine, and adjunct professor of dermatology and syphilology, Georgetown University School of Medicine, Louis Tulipan, M D, clinical professor of dermatology and syphilology, New York University College of Medicine, consulting dermatologist, Manhattan General Hospital, and associate visiting dermatologist and syphilologist, Bellevue Hospital, and Samuel M. Peck, M D, dermatologist, Mt. Sinai Hospital, New York City. Second edition, thoroughly revised 8°, cloth, 964 pp., with 146 illustrations and 1 colored plate Philadelphia Lea and Febiger, 1947 \$12 50

This second edition of a standard reference book has been revised to bring it up to date. Material on new chemicals and new methods of manufacture, many developed during the war years, has been incorporated in the text. The volume is well published in every way and should be in all medical libraries, as well as in the libraries of dermatologists and physicians coming into contact with industrial dermatoses.

NOTICES

ANNOUNCEMENTS

Dr. Sydney J. Allman announces the opening of an office at 422 Beacon Street, Boston, for the practice of dermatology and syphilology.

Dr. William J. Clauser announces the opening of an office at 330 Dartmouth Street, Boston, for the practice of psychiatry.

Dr. A. H. Delman announces the opening of an office at 183 Babcock Street, Brookline, for the practice of otolaryngology.

Dr. Howard A. Hoffman announces the removal of his office to 60 Eighth Street, New Bedford, for practice limited to urology.

Dr. H. Sinclair Tait announces the opening of an office at 142 Main Street, Brockton, for the practice of psychiatry.

Dr. Sidney C. Wiggin announces the removal of his office to 270 Commonwealth Avenue, Boston.

SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, October 21, at 12 noon. Dr. John H. Cauley, health commissioner, City of Boston, will speak on "Problems of the Health Department."

This meeting will mark the beginning of the twenty-first year for the South End Medical Club. Physicians are cordially invited to attend.

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY

The next meeting of the Middlesex South District Medical Society will be held at the Murphy General Hospital, Waltham, on October 22, at 12 noon, preceded by a business meeting at 11 30 a m. Various papers will be presented by members of the hospital staff. Luncheon will be served at 1 00 p m.

NORFOLK DISTRICT MEDICAL SOCIETY

A meeting of the Norfolk District Medical Society will be held at 8 p m. on Tuesday, October 28, at the Boston Medical Library, 8 Fenway, Boston, entitled "Lahay Clinic Night."

PROGRAM

The Present Status of the Peptic-Ulcer Problem Dr. A. Allen Wilkinson

Nonsurgical Proctologic Conditions Dr. Neil W. Swinton

Chronic Urethritis in Female Patients Dr. Earl E. Ewert

All physicians are invited to attend. A collation will be served.

CUSHING VETERANS ADMINISTRATION HOSPITAL

The following lectures will be presented at the Cushing Veterans Administration Hospital, Framingham, Massachusetts, at 4 p m. on the dates indicated.

October 24 Dr. John P. Peters, professor of medicine, Yale University School of Medicine "Some Problems of Edema"

October 30 Dr. Homer W. Smith, professor of physiology, New York University College of Medicine. "Hypertension and Urologic Disease"

October 31 Dr. Smith "Renal Circulation"

STATE-WIDE HEALTH LEGISLATIVE CONFERENCE

The fourth Annual State-Wide Health Legislative Conference will be held in the Gardner Auditorium, State House, Boston, at 10 a m. and 2 p m., on Wednesday, October 29. All those interested in health legislation are invited to present their projects at that time and, if possible, to send word of them and any bill drawn to the Massachusetts Central Health Council, 1148 Little Building, Boston.

AMERICAN ACADEMY OF ALLERGY

The American Academy of Allergy will hold its annual convention at the Hotel Jefferson, St. Louis, Missouri, from December 15 to 17 inclusive. All physicians interested in allergic problems are cordially invited to attend the sessions. As guests of the Academy by registering without payment of fee. The program and the scientific and technical exhibits have been arranged to cover a wide variety of conditions in which allergic factors may be important. Papers will be presented dealing with the latest methods of diagnosis and treatment as well as the results of investigation and research. Round-table conferences will be held on Monday afternoon, December 15. Advance copies of the program may be obtained by application to Dr. Charles H. Eyerly, chairman on arrangements, 634 North Grand Boulevard, St. Louis, Missouri.

CRITIQUE ON VAGOTOMY

WILLIAM R. MOSES, MD *

WASHINGTON, D. C.

AT LEAST fifty surgical procedures have been employed in the cure of chronic peptic ulcer since Doyen¹ first suggested gastroenterostomy, nearly all of which have been based on arrest or neutralization of acid secretion. The operation of the hour is vagotomy, which owes its popularity to the imperfections of its immediate predecessor, subtotal gastrectomy.

The criticisms of the end results of gastrectomy have been directed toward postoperative marginal and secondary ulcers, postoperative nutritional impairment, dyspepsia, diarrhea, defective fat absorption, secondary anemia, incomplete relief of pain, subsequent hemorrhages and "vagotonic symptoms." Postoperative ulceration is reported in 2 to 6 per cent of cases by Moore,² Zollinger,³ and Hollander and Mage,⁴ 31 per cent of 225 cases by Berg,⁵ 69 per cent of 173 cases by Kiefer⁶ and in over 100 cases collected by Hurst.⁷ Loss of weight has been noted in 10 per cent of 230 cases by Miller,⁸ 30 per cent by Ingelfinger,⁹ 47 per cent by Church and Hinton¹⁰ and 66 per cent by Browne and McHardy.¹¹ Ingelfinger⁹ found persistent postcibal symptoms, such as postprandial hypoglycemia, in 10 per cent. Diarrhea of minor degree is seldom encountered. Impairment of fat, but not of carbohydrate or protein, is rarely seen, but secondary anemia is frequent. Recurrence or incomplete relief of pain occurred in 36 per cent of cases according to Church and Hinton¹⁰ and in 40 of 502 cases in Colp's¹² series. Subsequent hemorrhages followed 46 per cent of resections in Kiefer's⁶ report, and mild "vagotonic" symptoms in 102 per cent of Berg's⁵ 225 patients. Miscellaneous "failures" are claimed in 10 per cent of Gatewood's,¹³ 30 cases and in 8 per cent of 26 cases studied by Garrett.¹⁴ Rienhoff¹⁵ believes that a certain number of complications are inevitable when gastric and jejunal mucosae are joined. In justice to the operation, however, it should be emphasized that its candidates are culled mainly from those refractory to medical management, that these reports do not represent general surgical experience and that the results of

the procedure in gastric as opposed to duodenal ulcer are consistently gratifying. Less than 1 per cent of these patients have further trouble.¹⁷ According to Walters¹⁸ marginal ulcer is almost unknown after resection for gastric ulcer. Finally, an operation for chronic duodenal ulcer that results in an average of 15 per cent failures in medically intractable cases is hardly ready for discard.

Although comparative results of medical and surgical therapy can be treacherous, a recent survey by Krarup¹⁹ is of interest. This study, based on the results of medical treatment after five years in 665 patients, reveals that only 29 per cent had a complete recovery, 36 per cent were improved and 35 per cent had a poor result. In the patients with gastric ulceration the relapse rate was 86 per cent, and those with chronic duodenal ulcer showed only 20 per cent complete recovery.

No surgical attack on chronic peptic ulcer can do more than break a link in the chain of ulcer pathogenesis, since the basic cause remains unknown. The factors modified, or supposedly modified, by vagotomy may be grouped as gastric secretion, gastric motility and gastric visceral sensation.

GASTRIC SECRETION

The hypothesis implicating hydrochloric acid excess in the pathogenesis of ulcer has recently been challenged by Sandweiss,²⁰ who found normal quality and quantity of secretion in patients with chronic ulcer but who agreed that this acid is irritative to the existing ulcer, he suggests that the stomach of the ulcer patient retains the acid for an abnormally long time—a view that is in conflict with the more generally accepted one of hypermotility. According to Palmer,²¹ there is abundant evidence that gastric secretion in patients with ulcer is above normal in acidity and quantity. Peptic ulcer, however, cannot be produced experimentally by perfusion of the intestine with any physiologic concentration of hydrochloric acid.²²⁻²⁴ Despite the dictum of Schwarz²⁵—"no acid, no ulcer"—achlorhydria was noted by Vanzant²⁶ with about half its frequency in the general population. Vanzant found that whereas the average duodenal

*Instructor in surgery, Georgetown University School of Medicine; assistant surgeon, Collinger Municipal Hospital.

ulcer has an acidity of 12 units above normal, the average gastric ulcer is accompanied by an acidity of 6 units below normal. Bloomfield²⁷ supported the general view that basal acid levels are increased in ulcer but observed normal levels on histamine stimulation. Acid values and total secretion are stated as increased in both types of ulcer by Sagal,²⁸ in duodenal ulcer alone by Bloomfield,²⁹ in the cephalic phase alone* by Necheles and Maskin³² and in all three digestive phases in duodenal but not in gastric ulcer by Ihre.³³ Dragstedt and his associates³⁴⁻⁴³ and Best⁴⁴ consider vagal hypertonus with hyperacidity, hypersecretion and hypermotility as pathogenetic. Hurst⁴⁵ recorded increased acidity and total secretion in 60 per cent of cases but questioned whether the finding is the cause or the effect of the lesion.

The role of pepsin, rather than acid, has been emphasized by Schiffrin and Ivy,²² Ihre,³³ Schiffrin and Warren,⁴⁶ Büchner,⁴⁷ Varco,⁴⁸ Bucher and Ivy,⁴⁹ Shoch and Fogelson^{50, 51} and Schiffrin and Warren.^{52, 53} The data include the discoveries that experimental ulcer cannot be produced by acid alone but can be caused if pepsin is added,^{22, 46, 52, 53} the finding of increased pepsin in the stomach of the animal with experimental ulcer⁴⁷⁻⁴⁹ and in man with ulcer³³ and the preservation of health in dogs with histamine-produced ulcer by simultaneous administration of sodium lauryl sulfate, which neutralizes pepsin without affecting acid.^{50, 51}

Dragstedt has repeatedly emphasized the role of continuous secretion in the persistence and initiation of chronic ulceration. This continuous secretion, which is estimated as from 10 to 117 cc an hour by Carlson,⁵⁴ Ivy⁵⁵ and Ihre,³³ may be abolished by atropinization, but the atropine effect is lost if an ulcer is present.⁵⁶ The biochemical effects of vagotomy are listed by Moore² as a drop of free hydrochloric acid to zero during most of the day, a rise of the reaction by 1 to 3 units constantly, a reduction of total acid, a mild drop in chlorides, no essential change in pepsin or total base and considerable reduction of total secretory volume.

In animals Pavlov⁵⁷ was the first to demonstrate gastric secretory fibers in the vagi and noted a loss of response to sham feeding after their section. Hartzell⁵⁸ produced a marked drop in free and total acid by vagotomy, but Vanzant,^{59, 60} studying the same dogs, found a gradual return to normal values in two or three years. Although Hartzell's work was confirmed by Dragstedt,^{36, 38} others have failed to do so in dogs⁶¹⁻⁶³ and monkeys.⁶⁴ Peptic ulcer has been caused in dogs by prolonged vagal stimulation.⁶⁵ Mann-Williamson dogs, which normally develop marginal ulceration, can be protected by vagotomy.⁶⁶ Ingestion of food results in a rise in gastric acid even though vagotomy has been

performed.⁶⁷ Vagal stimulation causes an increase in both acid and pepsin.⁶⁸

GASTRIC MOTILITY

According to Best and Taylor⁶⁸ vagal stimulation may cause either inhibition or stimulation of the gastric musculature, the effect being opposite to the pre-existing tone, but Wiggers⁶⁹ believes that the chief vagal effect is to increase the contractions while relaxing the pylorus. Dragstedt, Best,⁴⁴ MacKay⁴¹ and Shay⁷⁰ have found hypermotility as characteristic of the ulcer case, but Quigley⁷¹ states that most investigators have recorded normal motility, whereas Rivers,⁷² Todd⁷³ and the group of Sandweiss note decreased motility.

No such confusion regarding gastric motility is encountered after vagotomy, all authors reporting consistent, considerable and, at times, troublesome gastric atony with almost complete absence of hunger contractions, initial gastric emptying increased to fifteen or twenty minutes as compared to the normal of a half to one and a half minutes and complete emptying requiring fifteen to twenty-four hours in contrast with the normal of two to two and a half hours, this atony being typically limited to a few weeks or months.

GASTRIC VISCERAL SENSATIONS

The tenets of Hurst⁷ are accepted by most observers, who believe that the pain of peptic ulcer is due to spasm of the gastric musculature. Quigley⁷¹ holds that the pain is caused by violent hunger contractions, which are stimulated by mechanical irritation of the ulcer by food, fasting, elevated metabolic rate, cold, diabetes or hypoglycemia and inhibited by bland foods, smoking, pain and emotions. Direct chemical irritation of the nerve endings in the ulcer are considered the cause of the pain by Dragstedt and Palmer,^{21, 42} who reproduced pain without associated pylorospasm in human beings by direct acid application to the ulcer.

Whatever the mechanism of pain, its relief after vagotomy is dramatic and so consistent that post-operative absence of the phenomenon should suggest either inadequate operation or inaccurate diagnosis. Since radiologic and gastroscopic evidence of healing is delayed for one to three weeks and the relief is seen even when gastric secretion is relatively unaltered, one must suspect that the relief is neurogenic, even though it has been shown that afferent sensation from the stomach — as noted by response to hot and cold liquids, balloon distention and gastroscope traction — is unaltered. Dragstedt stated that the ingestion of acid after vagotomy reproduces ulcer pain, a contention not confirmed by Smith,⁷⁴ who concluded that pain is abolished by loss of ability of the stomach to enter the spastic state as a result of paralysis of its extrinsic nerve supply.

*The phases of gastric secretory response are classified by Schiffrin and Ivy²² and Ivy, Mellvain and Javols²³ as follows: cephalic phase, response to appetite, dependent on vagal tonus; abolished by atropine; gastric phase, stimulated by mechanical distention and secretion, not under vagal control; and intestinal phase, provoked by food, not intestinal secretagogue.

CRITICISMS OF VAGOTOMY IN THE DEFINITIVE TREATMENT OF ULCER

Although Dragstedt was the first to obtain successful results with vagotomy, the procedure was first employed by Latarjet¹⁶ in 1922, with early relief but later recurrence of distress. In 1930 Pieri and Tanfagna¹⁷ reported its use both above and below the diaphragm in 8 cases, with early depression but later restitution of acid after two years.¹⁷ In 1944 Weinstein¹⁸ found that resection of the vagi above and below the diaphragm in 6 cases had neither reduced acid nor afforded clinical benefit, a belief supported by animal experiments. Vagotomy has been criticized on the ground that it delays the passage of food into the duodenum and thus interferes with secretion of the hormone enterogastrone, which is normally released on contact of the duodenal mucosa with fat,¹⁹ inhibits gastric secretion and motility²⁰ and is believed to be of value in preventing experimental jejunal ulcer,²⁰ an effect also claimed for urogastrone.²¹ A further criticism is that the delayed gastric emptying results in prolonged contact of acid with gastric mucosa, and that the vascular supply to the stomach is decreased.²² An unfavorable view of the operation is taken by Sandweiss,²³ who objects to the numerous disturbances of intestinal function, the partial denervation of the pancreas and duodenum and the loss of "receptive relaxation" of the duodenum. Most observers have failed to demonstrate any important effects on pancreatic function.²⁴ Ivy²⁵ fears the predisposition to gastric atony and achalasia. Others will be disturbed by the failure to reduce pepsin secretion. Although a review of the literature shows that free acid is abolished in only half the cases and has a tendency to rise again after several months, proponents of the procedure believe that benefit has nonetheless resulted because the stomach is robbed of its ability to secrete super-concentrated acid juice during anxiety periods.

The technical difficulty of severing all vagal supply to the stomach by any approach has been emphasized,²⁶ and most modern enthusiasts have explained the consistent failures of the pioneer vagotomies by lack of thoroughness of the operation and failure to prevent regeneration of the fibers. White and Smithwick²⁷ have emphasized this remarkable ability of autonomic nerves to regenerate, a propensity that Moore has attempted to check by interposing the diaphragm between the cut vagi and Dragstedt has combated by using the parietal pleura as a block.

Although vagotomy per se is not criticized, its use should be avoided in the management of gastric ulcer. The resection for gastric ulcer is an exceptionally satisfactory operation, is attended by a mortality in capable hands of about 2 per cent, has consistently satisfactory end results and is almost never followed by recurrence or marginal ulceration.

Secondly, earlier resection of borderline lesions provides the single hope of improving the present egregious cure rate in patients with gastric cancer, less than 5 per cent of whom now survive five years. Using presently available diagnostic criteria, only the pathologist is able to differentiate gastric ulcer from early carcinoma. The radiologist, on whom this grave responsibility is usually thrust, fails in this differentiation in from 10 to 24 per cent of opportunities.^{17, 18, 27-29} When it is considered that cases so misdiagnosed represent the only group in which effective strides in the reduction of mortality from gastric cancer can be expected, these figures command respect out of proportion to their arithmetic values.

In my opinion, the most serious criticism that may be directed at vagotomy is that there is no incontrovertible evidence that it corrects the faults in the pathogenesis of ulcer, for the excellent reason that, despite the considerable physiologic alterations and consistent relief of pain, there is no proof that the factors so altered were at fault before the operation. The explanation of pain relief proposed by Smith³⁰ has been convincingly presented. Concerning ulcer healing, one must consider the consistent psychosomatic pattern peculiar to ulcer victims and the effects of medical and surgical suggestion in the neurotic type. All previous curative operations for ulcer were attended by phenomenal "cure" rates in their zeniths. Perhaps the ulcer-pain-ulcer syndrome is a vicious circle, which may be interrupted merely by relief of pain, but this hypothesis must await proof. In 2 cases reported recently by Weeks et al.³¹ fatal perforations of the ulcer followed vagotomy despite the relief of pain.

COMPLICATIONS OF VAGOTOMY

In this discussion the complications that are specific to the incisions, thoracotomy and laparotomy, or to anesthesia are omitted. The elimination of these, however, leaves certain actual or theoretical complications that are peculiar to vagus resection, such as failure to reduce gastric acid or its later recurrence, failure to effect ulcer healing or its recurrence, symptoms of gastric dilatation or pyloric obstruction, severe and persistent pain in the operative site, postoperative diarrhea, reduction of vascular supply to the stomach, cardiac and respiratory reflex effects and achalasia of the cardiac sphincter.

Although free gastric acid is completely abolished in about 50 per cent of cases, many have noted the inconsistent and unpredictable results in this respect,^{20, 26, 31-33} and these observations support the belief that reduction of acid is not the essential factor in relief of symptoms. Dragstedt³⁴ failed to abolish the cephalic phase of digestion as shown by response to a sham meal in 30 per cent of one series. In the Duke series even patients with an immediate achlorhydria demonstrated a return of acid within

several months⁷⁴ — a result anticipated from experience in animals.⁶⁰ There is no apparent effect on the gastric phase of acid secretion as shown by normal response to caffeine and histamine, which act directly on the gastric cells.

The insulin test* of vagal intactness, popularized by Dragstedt, is in general use as a test of adequacy of vagal section, and it is said that ulcer recurrence is unknown in cases in which the test has remained negative. The Duke group, however, found that the results of the test are inconclusive.⁷⁴

Ulcer healing after operation is not invariable, nor does healing guarantee against recurrence, as is shown by 1 case of early recurrence in the Duke series of 50 cases,⁷⁴ 2 noted by Crohn,⁸⁸ 1 by Dragstedt⁸⁸ in an early report and 6 patients with continuing distress in a later review.³⁶ Two fatal perforations after vagotomy have been recorded above. Weinstein⁶¹ noted no benefit in 6 patients studied. One recurrence and a postoperative stomal ulcer were encountered by Moore.² Curious and interesting has been the spontaneous development of gastric ulceration in vagotomized dogs and rabbits living under hardship conditions.^{103, 104}

Postoperative gastric retention occurs in almost all patients, although not usually to a degree sufficient to cause undesirable symptoms. Vomiting of transient or persistent nature, however, is the most frequent serious complication. Although marked gastric atony is usually limited to a few days, relative lack of motility lasts for several months, and if combined with narrowing of the pylorus or duodenal cap, due either to cicatrix or to edema, intractable vomiting will result. Such sequelae were noted by Dragstedt³⁶ in 3 cases, by Moore² in 1 case and in 10 per cent of the Duke series,⁷⁴ most of these patients requiring a second operation for relief of the obstructive phenomena. Occasional fullness and regurgitation were noted in half of 31 cases studied by Smith,⁷⁴ who found that mecholyl, prostigmine and doryl were of no value, but urecholine, suggested by Machella, was helpful in 4 cases in which it was used. If there is evidence of pyloric obstruction, either seen by the radiologist or felt by the surgeon, vagotomy should not be performed unless combined with gastroenterostomy, gastric resection or pyloroplasty.

Moderate to severe pain along the course of the intercostal nerves when the procedure is performed through the chest is frequent and often prolonged for six to twelve weeks. Section of the nerves during operation does not modify the discomfort, which is due either to crushing of the nerves between ribs jammed together by the rib spreader or to subluxation of the ribs at their sternal or vertebral attachments. Abbott¹⁰⁵ has used bromsalizol intercostal-

nerve block to relieve this pain during the first four to ten days after operation.

In the Duke series diarrhea was recorded in 54 per cent, being of extended duration in 16 per cent.⁷⁴ It was not relieved by the administration of acid by mouth, nor were there any abnormalities of stool fat. The symptom has been recently explained on the basis of jejunitis.

The criticism that vagotomy reduces the vascular supply of the stomach²² seems of dubious importance in view of the normally excessive blood supply, although Smith⁷⁴ reports a fatal case of rupture of pyloroplasty suture line among 6 cases in which vagotomy was combined with other gastric operations. Since pyloroplasty is often performed in scarred areas of decreased vascularity and in patients with general malnutrition, the role played by vagotomy in this accident is impossible to evaluate.

Cardiac arrest under anesthesia during manipulation of the vagi has been reported in at least 2 cases,^{2, 90} apparently owing to a "vagovagal" reflex — an effect that Moore² has avoided by the use of large doses of atropine before and during operation, in addition to novocainization of the nerves before manipulation. The high incidence of pneumonia (22 per cent) in the Duke series suggests that vagal manipulation predisposes to respiratory complications — a suspicion that is supported by experimental evidence in animal and man that vagal stimulation may produce slowing or arrest of the heart, fall of blood pressure, possible contraction of the coronary vessels and constriction of the bronchial system.^{67 106-119}

Although Ivy⁸⁴ stated that vagotomy predisposes to achalasia of the cardiac sphincter, the literature has been free of reference to this complication. It is difficult to understand why cardiospasm is not the usual effect. White and Smithwick⁸⁶ observe that the innervation of the esophagus includes the parasympathetic nerves, whose stimulation increases peristalsis of the esophagus and opens the sphincter, and the sympathetic, whose function is to inhibit peristalsis and close the sphincter. The vagi supply the organ directly as they lie in close contact with it in the lower third. The sympathetic motor and viscerosensory fibers arise from the fifth and sixth thoracic ganglions and those of the aortic arch. The lower esophagus and cardiac sphincter get their supply by way of the descending aortic plexus and splanchnic rami, running through the celiac ganglions and passing along the branches of the celiac artery, mainly the left gastric artery. Animal investigation of the effect of the vagus on the sphincter is confusing, some finding that the nerve is primarily a dilator to the muscle¹²⁰⁻¹²² and others that it is a constrictor.¹²³⁻¹²⁶ Most physiologists¹²⁷⁻¹³² believe that the dilatation of the esophagus after vagectomy is compensatory to spasm of the sphincter. Vagotomy in animals has been shown to result consist-

*This test developed from the studies of many observers³⁴⁻³⁹ who found that insulin hypoglycemia increases gastric motility and secretion — an effect that is dependent on the intactness of the gastric fibers of the vagus. In the test sufficient insulin, usually 20 to 30 units, is administered to lower the blood sugar below 50 mg per 100 cc. and is followed by intermittent gastric aspirations.

ently in achalasia^{123, 124-126} — an effect that may be prevented by previous or simultaneous sympathectomy¹²⁷⁻¹³¹ Knight and his associates¹³²⁻¹³³ and others¹³⁴⁻¹³⁵ have applied this experimental evidence clinically by sympathetic denervations of the gastric cardia in spontaneous achalasia, generally with indifferent results^{136, 137} Knight has explained the poor results obtained in other hands on the basis of failure to select amenable cases. He classifies muscular obstructions of the lower esophagus as achalasia of the cardia (due to vagal failure), cardiospasm (due to spasmodic contraction, a reflex disorder of other diseases, such as ulcer, esophagitis and neurosis) and hypertrophic stenosis of the cardia (exactly analogous to hypertrophic stenosis of infants). The first two conditions show no true obstruction and no muscular hypertrophy at autopsy, and both respond to sympathectomy. In the third type, the obstruction persists even after death and is, of course, unresponsive to sympathectomy. It seems that novocain block of the sympathetic nerves, followed by esophagram or esophagoscopy, should differentiate the types and suggest proper management. In the United States the favored operation is esophagogastrostomy.

The following is believed to be the first case report in which achalasia has been encountered after vagotomy.

J. H. S., a 44-year-old man, was admitted to Providence Hospital on October 28, 1946 with a history of 6 months duration during which he had suffered almost constant pain in the epigastrium and left upper quadrant partially relieved by the ingestion of sodium bicarbonate but not completely relieved by any measures including opiates. This interval was associated with a loss of 15 pounds in weight and intermittent red and tarry stools. In February 1945 a gastric resection had been performed for chronic duodenal ulcer after which the patient had been well until April 1946. Barium studies prior to admission revealed a marginal ulcer. Laboratory studies of the blood demonstrated only a secondary anemia. Gastric analysis recorded the free fasting hydrochloric acid as 62 units rising to 94 units after bicamine administration.

On October 31 supradiaphragmatic vagotomy was performed followed by Wengsten suction for 72 hours with progression to a soft diet on the 5th postoperative day.

On November 7 the patient remarked that his food seemed difficult to swallow but was reassured that the symptom was probably due to edema of the esophagus caused by manipulation, and was discharged on the following day, being greatly impressed with the total absence of abdominal pain since the first postoperative day.

On November 10 I was called to his home by the patient's wife, who stated that he was "choking to death" after eating some bread. He was attempting to vomit without effect and complained that the bread was stuck under the lower sternum, a sensation that was suddenly relieved after a swallow of water. An esophagram within 1 hour revealed the upper three-fourths of the organ to be slightly dilated whereas the lower 5 or 6 cm. was invisible for 4 minutes during which the barium column showed no change in level other than fluctuations coinciding with respiration. Gradually the barium began to trickle through the cardiac sphincter into the stomach. Three days later during which the patient was unable to swallow anything but small, frequent liquid feedings the esophagram was repeated with the same findings. A celiac ganglion block was then performed under bromalazolol after which the esophagram revealed normal transit. For the following 5 days the patient was able to swallow solid food without difficulty but on November 19

the symptoms recurred. Bromalazolol block was repeated on November 20 with the same results. On November 29, after a recurrence of symptoms the block was again attempted but the aorta was entered and the procedure was abandoned. Symptoms persisted for another week in milder degree than previously and then gradually disappeared. On December 14 the final esophagram revealed normal transit of barium although the esophageal lumen was dilated to twice its normal size. The marginal ulcer has healed radiologically and clinically and a weight gain of 17 pounds has since been noted.

This case demonstrates achalasia of the cardiac sphincter following vagotomy with symptoms of obstruction persisting for five weeks after operation. This is believed to be the first case report of this complication after section of the vagi, and is apparently the first of its treatment with celiac-ganglion blocks. It is impossible to know whether the final relief was due to bromalazolol, although the temporary alleviation may justifiably be assigned to the drug. That achalasia following vagotomy in animals has a tendency to spontaneous resolution has been suggested by Cannon,¹³² although Knight¹³³ believes that spasm persists but is functionally overcome by compensatory strengthening of the proximal esophageal peristalsis.

SUMMARY

Vagotomy in the therapy of peptic ulcer owes its popularity to the immediate and delayed imperfections of gastric resection. These criticisms of gastrectomy comprise postoperative recurrent and marginal ulcers, nutritional impairment, dyspepsia, diarrhea, defective fat absorption, secondary anemia, incomplete relief of pain, subsequent hemorrhages and "vagotonic symptoms," whose incidence collectively is about 15 per cent. The most serious delayed complication is marginal ulcer, which follows approximately 5 per cent of resections for duodenal ulcer. In competent hands the procedure will carry a mortality of about 3 per cent when the lesion is duodenal.

Medical therapy for peptic ulcer is not so successful as is generally believed, relapses being frequent and actual permanent relief occurring in as few as 30 per cent.

Gastric, as opposed to duodenal, ulcer should never be treated by any means other than gastrectomy, especially in the age group above thirty-five years. The inability of any available diagnostic measures to differentiate early carcinoma from benign ulceration with reliable consistency is well established. Secondly, gastric resection for gastric ulcer is an entirely satisfactory operation, almost never being followed by marginal ulceration. The mortality should not exceed 1 or 2 per cent, being lower than that in duodenal ulcer because the biliary structures are not in peril and the suture rows are placed in healthy duodenal tissue, minimizing the risk of blow-out of the duodenal stump.

Although semipermanent cures of ulcer are fairly consistently observed after vagotomy, the mecha-

nism of such cure is unknown, and its permanency cannot be measured within a generation. Not only is the pathogenesis of ulcer unknown but also there is lack of clinical and experimental proof supporting alleged disturbances of secretion and motility.

The salient effects of vagotomy on the stomach are a marked decrease in quantity and acidity of gastric secretion, although there is a strong tendency toward subsequent restoration to normal values, and impressive inhibition of gastric motility, also tending toward restitution. This depression of contractility of the stomach is of such a degree that vagotomy must not be used alone if there is evidence of pyloric or duodenal narrowing, but must be combined under such circumstances with gastroenterostomy or pyloroplasty.

The reported complications of vagotomy have been increasing in number and variety. The ulcer crater has occasionally failed to heal, or having healed, has recurred in a few cases. Whether this represents inadequate operation is unknown, but it must be emphasized that a most careful search should be made to assure interruption of all fibers. Gastric dilatation should be prevented by adequate postoperative suction and by cautious intake of food when some return of gastric tonus obtains. Persistent symptomatic gastric retention denotes some degree of pre-existing pyloric obstruction and contraindicates the use of vagotomy alone. Persistent pain in the operative area may be decreased by less vigorous rib spreading, by resection of two ribs to allow better exposure with less retraction or by the use of the abdominal approach. Cardiac asystole during operation may be avoided by adequate atropinization. What is apparently the first case of achalasia after vagotomy in man is reported, and its management with bromsalizol celiac-ganglion blocks is discussed.

Vagotomy is indicated in two situations as the procedure of choice — marginal ulcer, whose relief by conventional means involves a procedure of first magnitude in a patient usually in only fair or poor condition, and duodenal ulcer, especially the type penetrating the pancreas or involving the area of the common bile duct or ampulla. These are the types that contribute most to mortality rates and technical difficulties.

COCCIDIOIDOMYCOSIS IN NEW ENGLAND

EDWARD R. H. KURZ, M.D.,* AND NORMAN W. LOUD, M.D.†

WHITE RIVER JUNCTION, VERMONT, AND BROOKLYN, NEW YORK

COCCIDIOIDOMYCOSIS, probably the most infectious of the systemic mycoses, is rarely found along the Atlantic Seaboard. Owing to the tremendous displacement of people from their native areas that occurred during the war, however, clinicians must be aware that these infections may occur among the population, particularly in persons who have seen service in endemic coccidioidomycotic areas. A carefully taken history in patients who present granulomatous conditions of the skin and bizarre pulmonary lesions, either of cavitation without surrounding exudation or of ring-like apical formations with negative tuberculin, as well as a period of residence in areas where coccidioidomycosis is present, should make one suspicious of this condition.

The purpose of this article is to report a series of 4 cases of coccidioidomycosis found in servicemen who had returned to their native environments, particularly in the area of New Hampshire and Vermont, with lesions that resulted in the determination that they had sustained coccidioidomycotic infections. One of these cases presented a severe granulomatous condition of the skin that was not recognized for a long time, was extremely disfiguring and responded to therapy only after many extensive trials with penicillin, streptomycin, sulfonamides, iodides and x-ray therapy alone and in combination with penicillin.

The pathologic process may be divided into two clinical phases—namely, the primary type of coccidioidomycosis, particularly of the pulmonary variety often spoken of as "valley fever" or "San

Joaquin fever," which has its early infection some nine days after exposure and is characterized by mild upper respiratory manifestations such as a low-grade fever—(temperatures of 99 to 101°F) and the type having backache and headache. In some of these primary cases, skin lesions resembling erythema nodosum occur and then disappear after a few days. All primary infection and roentgenographic evidences of pulmonary disease are frequently lacking, and when infiltrations of the lung occur, they are usually small and resolve within several weeks. In some cases the lesions show progression rather than spontaneous resolution, and with rare exceptions, no primary cutaneous infections are reported. In the majority of cases, however, the disease progresses into the phase of remission, and the asymptomatic patient usually continues for a long period until—by either a routine x-ray film or, as in 1 case reported below, a cutaneous lesion manifests itself—the process is recognized. In cases that go on to terminal courses, the symptoms are often referable to organs showing a mass of lesions, especially the lungs, the lymph nodes, the meninges and, occasionally, the skin. Clinically, roentgenographically and anatomically these visceral lesions may resemble tuberculosis, blastomycosis or one of the lymphomas.

From an x-ray standpoint, the lesions in the films usually demonstrate one of several patterns. In the early stages they may show nothing but soft, fuzzy, hilar thickenings, if the disease is more advanced, examination may disclose a pneumonic type of infiltration usually extending from the hilus into the middle or lower lung fields. In cases that have undergone recrudescence, to which this paper is largely confined, the most characteristic finding is

*Chief of medicine, Veterans Hospital, White River Junction, Vermont.
 †Assistant attending physician, Brooklyn Hospital.

†Chief, Radiological Department, Veterans Hospital, White River Junction, Vermont.

that of well isolated and well circumscribed, nodular lesions in the parenchyma of the lung. Such nodules are 2 or 3 cm. in diameter, occurring most frequently in the middle or lower lung fields. They usually occur singly, but sometimes they are multiple. The lesions are benign in character and after a period of months they either resolve or develop into thin-wall, cyst-like cavities. Such cavities may disappear and shrink to small nodules, which may become calcified, or they may persist for years. In 1 case, in frequent follow-up examinations, the cavity regressed and increased in size on several occasions, although the patient was asymptomatic.

The diagnosis is usually sustained by a positive skin test using the antigen of *Coccidioides immitis* or, in the patients with skin lesions, by a biopsy from the granulomatous area. The organism is easily recognized as a large (20 to 80 microns in diameter) cell whose wall is thick and doubly refractile and occasionally shows a fringe of radiating eosinophilic substance projecting from its outer layer. In all the cases presented below we were able to obtain positive skin tests to the coccidioidomycotic antigen supplied by Dr. C. E. Smith, of the University of California, and in the case with skin lesions we were able to substantiate the diagnosis by the biopsy method (Fig. 1).

The first case was observed by virtue of the fact that the patient presented himself for treatment be-

treated unsuccessfully on the outside for six months to a year without any improvement, and the under-

FIGURE 1. Photomicrograph of a Biopsy Specimen from the Skin. This shows a typical coccidioid organism.

lying picture was not ascertained until his arrival for definitive hospitalization.

CASE REPORTS

CASE 1. E. R., a 34-year-old machine worker residing in Manchester, New Hampshire, entered the hospital on Sep-

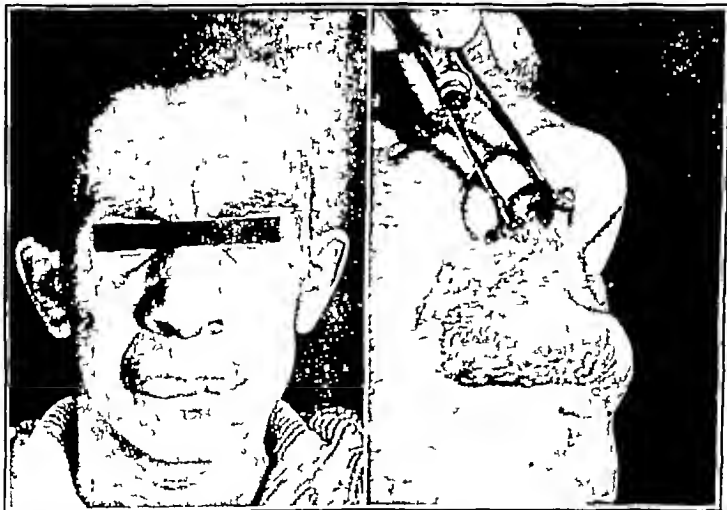

FIGURE 2. Photographs Showing the Swelling of the Upper Lip and the Nasal Lesion on the Right.

cause of the development of a severe, ulcerative, granulomatous lesion of the nose, which had been

tember 9, 1946, with a history of a swelling of the upper lip of 10 weeks duration. He stated that for the previous year he had had an ulceration on the inner medial portion of the

left nostril that had resisted all methods of treatment and, for 6 months prior to admission, had also occurred in the right nostril. Ten weeks before admission a severe, pronounced swelling of the entire upper lip, with excoriations on the mucosal side of the lip and with cracking and fissure formation, had developed. The patient stated that about 1 year previously, in the Normandy invasion of 1945, he had been awakened suddenly while sleeping under a wagon and, in his haste to arise, had struck his left cheek against the

two deep fissures measuring 1.5 cm in length dividing the upper portion of the lip. In addition, the nose revealed a crusted ulceration on the border of the inner side of each nostril (Fig 2), the ulceration was grayish and measured 1.5 cm in diameter. The entire encrusted area was granular in appearance and dry, and there was no exudate. The lesion felt hard to the touch. Examination of the rest of the system was essentially negative. The chest expansion was good, no rales were heard either at the apices or at the bases, and

FIGURE 3 Case 1

This roentgenogram of the chest, taken shortly after admission to the hospital, shows a ring-like shadow of increased density in the first interspace

tongue of the wagon. This incident had been followed by swelling of the left cheek for a period of 2 weeks. When the swelling of the cheek had subsided the small, ulcerative area in the left nostril, which persisted to the date of his discharge from the Army and to the time of admission, had developed. In the statement of service it was revealed that this patient had been a corporal in the Field Artillery and had served from June, 1943, to December, 1943, in the Indio Desert, California. At the time of his service there he had never been ill, he remembered having nothing other than a mild respiratory infection for which he did not think he had required treatment.

The past history was essentially noncontributory, except for chicken pox in childhood and a hemorrhoidectomy in 1941. The venereal history was entirely negative.

Physical examination revealed a large swelling of the entire upper portion of the upper lip (Fig 2), with encrustation of the mucous membrane of the inner side of the lip and

there was no change in the character of the breath sounds. No other skin lesions were noted.

The blood pressure was 105/80.

Examination of the blood disclosed a red-cell count of 5,260,000, with 16 gm of hemoglobin, and a white-cell count of 6950, with 67 per cent neutrophils, 26 per cent lymphocytes, 3 per cent monocytes, 2 per cent eosinophils and 2 per cent basophils. Urinalysis was normal, and the Mazzoni and Frei tests were negative. A test smear for Vincent's organism of the lesion was also negative, as was a skin test for tuberculosis and a patch test. The sedimentation rate was 4 mm in 1 hour. X-ray examination of the chest showed scoliosis of the dorsal spine and convexity to the left at the fifth dorsal segment. The trachea was in the midline. Both leaves of the diaphragm were clearly outlined, and the costophrenic angles were clear. The right lung field was essentially clear, and the left revealed a ring-like shadow of increased density in the first interspace, with a slight increase

in the bronchial markings radiating toward it (Fig. 3). X ray findings were interpreted to suggest an old acid fast infection that had been controlled.

A biopsy of the encrusted area of the lips and of the ulcerated areas of the nose was performed 2 weeks after admission. The pathological report showing tubercles containing giant cells filled with fungi. The fungi revealed a high refractile border without budding and with endosporeulation. This was consistent with the picture of cutaneous coccidioidomycosis.

A review of the x ray films of the lung at that time showed a picture more consistent with coccidioidomycosis than with

the patient made a remarkable response. The swelling decreased rapidly to the point that it was only slightly noticed.

Two months later a second biopsy was performed by the taking of a section from the skin area of the inner side of the nostril, with the following report: A firm gray white fragment measuring 0.3 cm. reveals squamous epithelium overlying inflamed connective tissue. There is no evidence of specific inflammation.

A second course of radiation given at the Mary Hitchcock Clinic by Dr. Leslie Sycamore consisted of 400 r to the lip and 400 r in each side of the face to a total of 800 tumor

FIGURE 4 Case 3

In this roentgenogram there is a circumscribed cavitation in the right upper lobe

tuberculosis. A skin test for *C. immitis* was positive. The patient was given 1 gm. of sulfadiazine every 4 hours, with equal amounts of sodium bicarbonate, for 7 days without any change in the character of the lesion. This was followed by 0.6 gm. of potassium iodide daily with similar poor results. The patient was then placed on 1 gm. streptomycin daily being given 0.25 gm. every 6 hours so that he received in all 30 gm., without any result. Penicillin, in doses of 50,000 units every 4 hours for 10 days, was then administered without any improvement. This was followed after a rest period of 8 days, by five doses of x ray therapy of 200 r each on alternate days to the lip and the ulcerative area so that he received a total of 1000 r. Approximately 10 days later the entire lip became macerated and red and the edema increased until the lip was twice the normal size. Because of the intensity of the reaction, penicillin in massive doses was given the amount being 10,000,000 units in 7 days to which

dose r. This resulted in complete recession of the lip and nostril lesions, with loss of the edema.

During all this treatment there was no change in the character of the lung lesion.

CASE 2. A. P., a 22-year-old man whose home was in Manchester, New Hampshire, gave a history of having been admitted to a hospital at Laredo, Texas, on November 18, 1943, for headache, dizzy spells, heartburn, and palpitation of several years duration. Physical examination during the entire period of hospitalization had been negative and because of his complaints the patient had been adjudicated psychoneurotic and given a discharge from the Army after a hospital stay of 40 days for this condition. X ray films of the lungs as reported on October 13, 1942, were normal. X ray study in the hospital in Laredo also revealed normal lungs. He reported here on October 14 for the treatment of a draining pilonidal sinus. X ray examination showed a thin-

well cavitation in the left infraclavicular region whose etiology could not be determined. A repeat x-ray film on February 16, 1946, with a skin test, showed a positive reaction for coccidioidomycosis. The x-ray film of the chest in the posteroanterior view revealed a definite ring shadow in the left infraclavicular region opposite the second interspace anteriorly. There was little reaction around the shadow. The lung fields were otherwise clear and radiant. Check-up examinations at frequent intervals have shown this lesion

upper lung (Fig 4). The remainder of the lung fields were essentially normal. Extensive laboratory studies revealed a sputum analysis that was negative for tubercle bacilli and coccidioidomycosis. A skin test for coccidioidomycosis was also negative.

A closer investigation into the history revealed the fact that the patient had served from January to April, 1942, on maneuvers in southern Arizona where he had been hospitalized for an upper respiratory infection. The Mantoux test

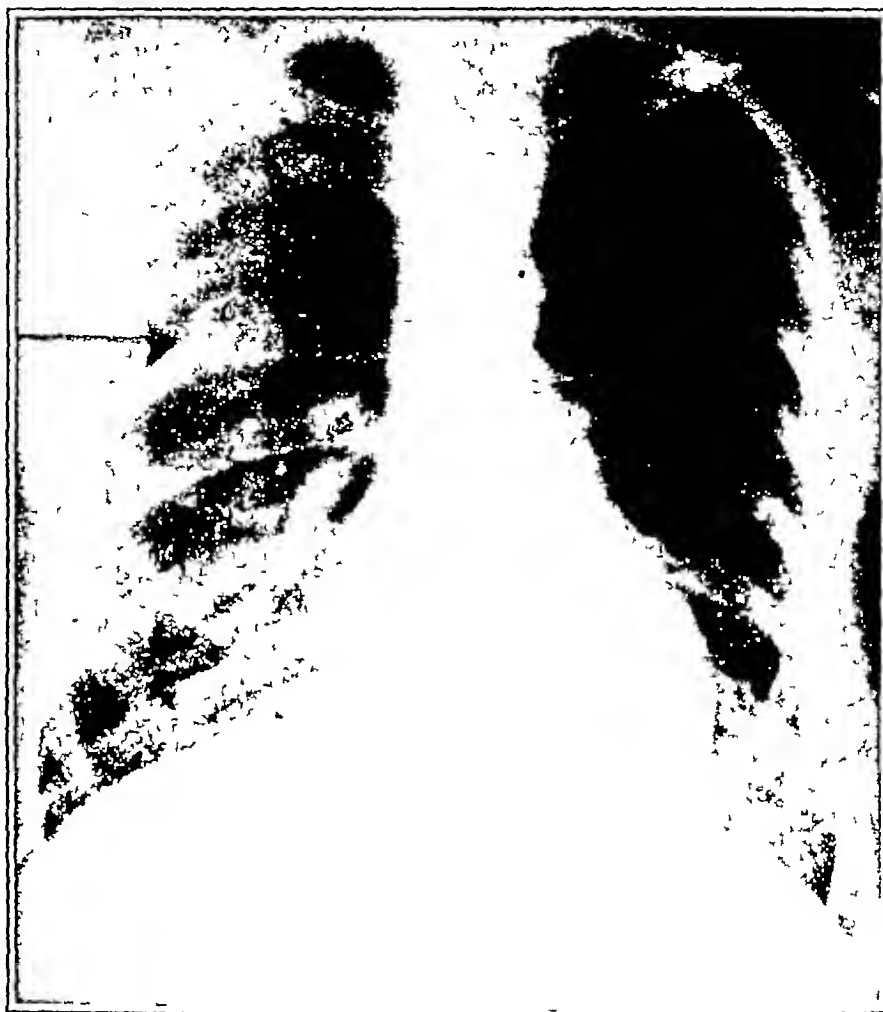

FIGURE 5 Case 3

This roentgenogram, taken over eight months after the one illustrated in Figure 4, shows that the lesion in the right upper lobe has apparently increased in size

to vary in size, sometimes increasing and at other times looking slightly smaller.

CASE 3 L R B, a 34-year-old man, had served for 10 months overseas as a technician, Grade 4, in a hospital unit. In his history of service he stated that he had been hospitalized on Guam in November, 1944, because of a skin condition. This condition was diagnosed later by culture as a diphtheritic skin lesion of the left foot, which responded to 30,000 units of penicillin. He remained in service until February 10, 1945, when he was discharged. He was admitted here in August because of a chronic acne of the face and back.

Physical examination revealed an asthenic patient with a marked lymphosis. There was moderately advanced acne of the back, characterized by papulopustular lesions and marked scarring. The remainder of the physical examination was essentially negative.

Routine x-ray films of the chest taken on September 18 disclosed a well defined 1.5-by-1.5-cm cavity of the right

at this hospital was negative. The skin condition was treated here, and biopsy of the lesions of the back revealed several cysts lined with hyperplastic, squamous, stratified epithelium. The lumen was filled with desquamated, keratinized epithelium. There was intense infiltration of the adjacent tissue by polymorphonuclear leukocytes, foreign-body giant cells and lymphocytes. The diagnosis was that of multiple cholesteatomas. X-ray study on February 6, 1946, revealed the cavity of the right upper-lung field to have decreased in size. Examination on June 12 showed slight enlargement of the cavitation of the right upper lobe as compared with previous x-ray findings (Fig 5).

CASE 4 F D, a 30-year-old native of Montpelier, Vermont, was admitted to the hospital in April, 1945, for the removal of a pilonidal sinus. Routine x-ray study revealed a small cavitation, 1 cm in diameter, in the left upper lobe. Questioning disclosed that the patient had served in the

Indio Desert, California, for 8 months in 1942 but that he had had no illnesses while there.

A skin test was positive for coccidioidomycosis (immunity), and the patient was carried as an additional case.

Discussion

The 4 cases presented above were in the subsiding phase, with minimal residual evidence of the pulmonary infection in the lung. The 1 clinically active case, showing the unusual lip lesion described, also revealed only the residual ring shadow in the upper left lung (Fig. 3).

The clinical course has been well correlated with the roentgenologic findings in this disease by Sweigert, Turner and Gillespie, who divide the roentgenologic manifestations of primary coccidioidomycosis as follows: pneumonitis, 70 per cent, adenitis, 23.3 per cent, cavitation, 7.8 per cent, nodules, 5.2 per cent, pleural effusion, 2.6 per cent, and normal chest, 2.6 per cent.

The pneumonitis may be slight and barely visible on the x-ray film, or multiple areas of the lung may be involved with a considerable infiltration, but the statement is made that "consolidation of an entire lobe is extremely rare." These infiltrations may resolve in one to four weeks, but usually complete resolution does not occur. There are, then, two courses: either healing and fibrosis may predominate, or cavitation results from focal necrosis in the involved lung area. The cavity may then gradually disappear, or residual scarring may persist. It is possible that the ring-like shadows demonstrated in the cases presented above were chiefly residual scarring.

Sweigert et al. describe two types of cavity formation, one occurring in an area of pneumonitis with focal necrosis. "This type of cavity is quite thin-walled and is likely to be irregular in contour. These cavities frequently persist for more than a year and may vacillate in size to the extent of increasing in volume, after having decreased markedly."

One of the cases presented above (Case 3) demonstrated this feature (Fig. 5). This man had had numerous chest films from December, 1944, to September, 1946, showing only a small residual nodular lesion in the film of December 3, 1944, taken in the Ninth General Hospital. The lesion was then circular and 1.5 cm. in diameter, without noticeable cavitation. It increased gradually through a period of six months at Lovell General Hospital from 1.7 by 2.2 cm. to 3.0 by 2.3 cm. (six examinations from February 16 to August 28, 1945). It was in the larger phase when he entered the hospital — measuring 3.0 by 2.5 cm. on the film. All subsequent films were taken at the same distance with the patient carefully positioned so that the chest diameter was the same on all subsequent films. Again the cavity diminished from the above measurement to 1.7 by 1.3 cm. in diameter on June 3, 1946. Monthly films disclosed gradual diminution, but the film of Septem-

ber 12 again showed a slight increase, when the ring shadow measured 1.8 by 1.8 cm.

Apparently, in spite of these changes in the appearance of the pulmonary lesion, the condition was symptomatically quiescent and the patient had no complaints referable to the chest.

Adenitis, hilar and mediastinal, is a usual accompaniment, listed as 23.3 per cent but probably somewhat higher, since prominent nodes may appear in both the mediastinal and the hilar areas, subsequently returning completely to normal, with no evidence of the disseminated phase at any time.

The only case showing the nodular phase described by Sweigert et al. was also the case that demonstrated the variability of the lesions, and in that case the cavity was thin walled and somewhat irregular in outline.

None of the cases showed evidence of pleural effusion during the periods under observation at this hospital.

* * *

The cases reported above revealed nothing new so far as the occurrence, geographic distribution and character of the disease are concerned. There are, however, several interesting facts that have developed — clinicians along the Atlantic Seaboard must be aware of this condition, and it may be expected to occur among personnel seen away from their previous locations. In addition, there is brought forth the urgent necessity for frequent x-ray examinations of persons who have been in areas endemic for coccidioidomycosis, skin lesions developing in such people, particularly of a granulomatous nature, should be carefully studied for the presence of the fungi.

From the standpoint of differential diagnosis, if coccidioidomycosis is kept in mind and histories of the possibility of exposure are carefully taken, there should be no difficulty in separating these cases from tuberculous infections, particularly in the late stages that are likely to be picked up in this community. The ring shadows are fairly sharply defined, and there is no reaction around them. There are no "flaky" or hazy shadows in the surrounding lung parenchyma, and in this limited series the lesions were solitary, without other reaction in the chest.

Metastatic cancer and bronchiogenic carcinoma may also be simulated, but the multiple lesions in the former and the absence of atelectatic areas in coccidioidomycosis should serve as differential features. Positive skin and serologic tests help to confirm the radiographic findings.

Lastly, the case with the skin lesion represents a decided cure under x-ray therapy, and the advantageousness of this therapy is well illustrated by the intractability of the lesions to all other recognized forms of therapy, such as the sulfonamides, penicillin, streptomycin and the iodides.

PSYCHOTHERAPY IN GENERAL MEDICINE*

Report of an Experimental Teaching Unit on a One-Hundred-Bed Medical Service

HENRY M. FOX, M.D.†

BOSTON

IT HAS now become generally recognized that in some way must be found to teach medical students and house officers the kind of personal therapy that has always been carried out by the family physician without his even being aware of the fact that he was doing anything unusual. Modern conditions of medical practice, with increasing emphasis on specialization and with the growth of large urban medical centers, have made it increasingly difficult for patients to be understood in terms of personal history in a family setting. The discoveries of psychiatry during the course of the past fifty years concerning the psychology and the physiology of the emotions have become so well established that it is no longer fair to the young physician or to his future patients to send him out into practice without carefully planned instruction along these lines. The whole question of what to teach and how to go about it has become a matter of general concern, especially since the experiences of the recent war have emphasized the importance of psychologic factors as a cause of disability among large numbers of supposedly healthy young men and women.

General Organization

To supplement the regular instruction in psychiatry along these lines the Departments of Medicine and Psychiatry at Harvard Medical School have established a special medicopsychiatric teaching

*From the Medical Clinic, Peter Bent Brigham Hospital, and the Department of Psychiatry, Harvard Medical School. This project was made possible by a grant from The Commonwealth Fund.

†Assistant professor of psychiatry, Harvard Medical School; senior associate in psychiatry, Peter Bent Brigham Hospital.

unit, which has been in operation for over a year at the Peter Bent Brigham Hospital. The general organization of this unit is presented in Figure 1. The purpose has been to demonstrate methods of psychologic treatment appropriate to the care of patients admitted to general-hospital wards because of illnesses requiring medical or surgical supervision. Special emphasis has been placed on working out a program for teaching the emotional factors in medical practice to third-year and fourth-year medical students, as well as to the house staff of the Peter Bent Brigham Hospital. The unit has functioned as an integral part of the Medical Service, and the relation of members of the unit to the medical house staff has been that of consultants. Clinical responsibility for patients admitted to the hospital has been left in the hands of the medical staff, and house officers have been encouraged to make use of psychiatric consultations to give them a better understanding of the patient and to stimulate interest in the personal factors affecting the illness. Establishment of a separate psychiatric service was carefully avoided, since this would have made it too easy for the house staff to turn over patients with any sort of emotional problems to someone else instead of working with these factors along with the manifestations of physical disease. It was found that many of the patients with clearly demonstrable organic abnormalities were as much disabled because of their emotional reaction as they were because of the disease that had provided their ticket of admission to a medical or a surgical service.

There were also many patients presenting difficult diagnostic problems that could be solved only by a careful consideration of the psychologic data. Finally, there were cases of duodenal ulcer, mucous colitis, asthma, hypertension, hyperthyroidism and various other clinical entities in which the importance of the emotional factor has been generally accepted.

Selected patients have been treated by members of the unit during a series of outpatient interviews following discharge from the hospital. The therapeutic results have been used to illustrate the role of the specialist in the treatment of general medical cases. It has been the policy of the unit to work particularly with patients of a type likely to consult

such a way as to bring out the importance of family relationships, the role of anxiety as an expression of powerful internal conflicts in contrast to more specific fears related to real dangers in the objective world and finally the bearing of both family relationships and neurotic anxieties on the therapeutic possibilities of the patient-physician relation. During the past year the teaching program has been planned especially for third-year and fourth-year students at Harvard Medical School and for members of the medical house staff.

Teaching of Fourth-Year Medical Students

Fourth-year students at Harvard Medical School are assigned to the Peter Bent Brigham Hospital for

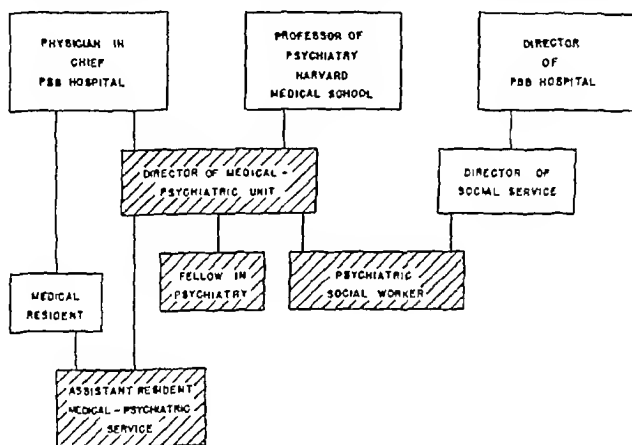

FIGURE 1 *Chart of Organization*

a general internist or a general surgeon and to share psychiatric training with internists and surgeons, who will themselves have to handle many of the patients presenting psychologic problems. Even if it were possible to refer a far greater number of patients to psychiatric specialists, it seems highly desirable for all physicians to acquire a much greater understanding of the psychology of their patients than most of them now possess. The unit has therefore directed its efforts toward the demonstration of improved methods for the handling of patients in the general medical and surgical situations, and the nature of the more fundamental make-up of the patient has also been brought out to provide a better understanding of the way in which long-standing emotional patterns contribute to the production of current symptoms.

It has been found desirable to organize case presentations at clinics and for student conferences in

their medical work over a period of two or three months. There are usually six to eight students on the Medical Service at one time. The students are seen by the staff of the unit for teaching conferences three times a week. One day each week, the students gather for a seminar discussion of some general topic, such as the technique of the interview, anxiety as an expression of internal conflict, the bearing of family relationships on illness, the emotional implications of chronic disease, the evaluation of suicidal risk on a general medical or surgical service, discussion of psychiatric referral with illustrations of psychotherapy as carried out by the specialist, the use of psychiatric and general medical social service or various phases of normal emotional development, including particularly the general problems associated with adolescence, choice of vocation, marriage and retirement. In addition, a second hour is devoted on another day to the pres-

entation of a current case from the Medical or Surgical Service. Each of these patients has been seen at least two or three times by one of the staff of the unit so as to make sure that the relevant psychologic material is available for discussion and demonstration. Active participation in the discussion by the students has been achieved without much difficulty.

After the first few months, it was found desirable to add to this program a third hour, which is now considered perhaps the most important of all. This consists of a private conference each week for each student with the director of the medicopsychiatric unit. Each student is thus interviewed alone anywhere from eight to twelve times during his service on the medical wards. These conferences are made as flexible as possible so as to allow the student not only to discuss the facts of the cases he is attempting to handle but also to talk over whatever personal difficulties he may have with the patient-physician relation. It has thus been possible to work out some of the personal difficulties that lead students to resist discussion of emotional or psychologic data. One student, for example, was having considerable difficulty relating his interest in the emotional problems of his patients to his own strict and highly intellectualized Roman Catholicism. He expressed himself as feeling personally much more at ease after the conclusion of his three months on the Medical Service, and his ability to work with a wide variety of patients was, he believed, considerably enhanced. Another student was puzzled over his destructive impatience when taking a history of boys from the ages of fourteen to eighteen. After a few discussions of his own emancipation problem, he reported that he was having no difficulty in dealing with the boys assigned to him, and his general capacity for working with all sorts of patients was quite noticeably improved. We were much encouraged to find that ever since the institution of this third hour we have had 100 per cent attendance at all clinics and seminars.

Teaching of Third-Year Medical Students

Third-year students at Harvard Medical School are assigned to the Peter Bent Brigham Hospital for a period of twelve weeks. They usually come in two groups of four to six each. The medical teaching program includes training in the taking of histories and the performance of physical examinations followed by work with a series of patients for a week at a time. Each student thus sees from eight to ten patients during his twelve weeks on the Medical Service. The medicopsychiatric unit participates in this program. Each group of four to six students is given instruction concerning the methods and content of the personal history, family relationships, anxiety as the expression of neurotic conflict and the importance of repeated interviews being stressed to establish enough of a patient-physician relation

to make it possible for personal material to be shared by the patient with the physician. This teaching conference immediately follows the two introductory sessions by the general-medical-staff members on history taking and the physical examination. In addition to this general discussion, each student is assigned to a case selected by the medicopsychiatric unit for a period of one week. The student is supervised by the psychiatric fellow or by the assistant resident of the medicopsychiatric service, and at the end of the week each student has an hour's conference with the director of the unit. It has been found that the students are highly receptive to this sort of instruction at this period when they are just beginning to interview their medical patients. This individual instruction is reinforced by clinical demonstrations and case presentations to larger groups of the third-year students. During the course of the year every member of the third-year class at Harvard Medical School attends at least two such clinical demonstrations at the amphitheater of the Peter Bent Brigham Hospital.

Teaching of the House Staff

All the assistant residents report each morning to the physician-in-chief, briefly describing the new patients who have been admitted during the previous twenty-four hours. The director of the unit has been welcomed as a participant in these morning sessions and has thus had the opportunity to indicate personality factors that may be playing a part in the diagnostic and treatment problem of patients as they enter the hospital. The wholehearted support of the physician-in-chief has been a most important influence in the establishment of the program.

The psychiatric fellow and the assistant resident of the medicopsychiatric service each have an office on one of the two largest medical wards. This has provided direct and intimate access to the patients on the ward and has also made it easy for members of the house staff to talk things over informally with members of the unit.

At the request of the physician-in-chief a more formal course was organized for the instruction of the members of the house staff. The interns were given what amounted to eight seminar sessions, which all of them attended. Each topic was illustrated by case material from patients recently admitted to the Peter Bent Brigham Hospital. The topics were as follows:

January 6, 1947 *Psychotherapy* — the use of psychologic measures in the treatment of sick people

Altering the *environment* by talking to a relative, dealing with the employer, discussion with the minister or teacher or changing the living arrangements with the help of social service

suggesting diversions, hobbies and so forth or advising a vacation

Supportive treatment by reassurance, physiotherapy, suggestion and the use of pharmacologic aids in the setting of the patient-physician relation

Helping the patient to *understand himself* better This ranges from providing release from emotional tensions through giving the patient an opportunity to express himself to an interested and informed but noncondemning person, to the establishment of a special relation to the therapist, which makes it possible for repressed emotions to emerge into consciousness The latter requires a carefully trained specialist.

January 7 Neurotic symptoms and various physiologic disturbances as ways of dealing with anxiety Realistic fears—for example, the reaction to disabling illness or old age—contrasted with neurotic anxiety arising from a dangerous conflict of forces within the personality

January 13 Growth of personality in *childhood* Influence of emotional relations to parents and siblings on habits of eating, sleeping, bowel and bladder control, and play activity at different ages Patterns of dependence and overprotection, sibling rivalries and their influence on personality development

January 14 Psychology of *adolescence* or the process of emotional emancipation from the family, psychosexual maturation ("crushes," hero worship, sex phantasies), nature of the storms and stresses in girls (menarche) and boys

January 20 *Vocational* choice, satisfaction and dissatisfaction in the setting of relations to superiors, inferiors and equals, particularly as influenced by attitudes toward authoritarian figures, personal patterns of rivalry, need for prestige and self-assertion, drive for security and reaction to responsibility

January 21 Psychology of *marriage*—biographical factors influencing the personal and sexual adjustment (Adjustment to masculine and feminine roles)

January 27 Patient-physician relation in terms of personal attitudes on the part of

The patient—especially attitudes of dependence on parental substitute,

and the physician (tendency to identification with the patient—"sympathy"—or the rejection of the patient—"impatience"—because of the doctor's own conflicts)

January 28 Technique of the *interview*—maintenance of interest through nonleading questions, avoidance of argument, "throwing the ball back" to the patient, following up leads, letting patient paint his own picture and so forth

Suggested reading included *The Happy Family*, by Levy and Monroe, *The Parents' Manual*, by Anna W. M. Wolf, *Baby and Child Care*, by Benjamin Spock, and *Psychotherapy in Medical Practice*, by Maurice Levine

All the sessions were conducted by the director of the unit, except for the session on childhood Dr. Marian C. Putnam, the director of the Children's Center at Roxbury, was kind enough to give this talk.

Although the interns at first manifested an attitude of polite and rather cool skepticism, it was quite evident that as the sessions progressed their enthusiasm and active participation increased to a gratifying extent.

These seminar sessions were followed during the month of February by four sessions (one a week) with patients in the Out-Door Department under the supervision of a senior psychiatrist.* Each psychiatrist supervised two interns an afternoon for four afternoons. Most of the interns were quite enthusiastic about this type of instruction, and all of them were interested. The psychiatrists were also quite enthusiastic. The chief difficulty encountered was the selection of patient material. This responsibility had been left to the individual house officers, and it turned out that they really needed much more guidance than we had been able to give them in this matter. Quite a number of the interns plan to follow their patients for a period of several months, and several of the psychiatrists have agreed to make themselves available for further instruction and guidance. Since the presentation of this course, there has been a noticeable alteration in the general attitude toward the work of the medicopsychiatric unit on the wards, and this has had a particularly favorable influence on the medical students, who were previously somewhat discouraged by the skepticism of the house officers.

Personnel of the Unit

The director of the unit was given an appointment in the Department of Psychiatry of Harvard Medical School, as well as an appointment on the Medical Service of the hospital. A psychiatric fellow and an assistant resident of the medicopsychiatric service have carried out psychiatric interviews on all the patients presenting emotional problems of any importance to the Medical Service, which contains one hundred beds, and they have also seen a number of patients on the Surgical Service as well. Copies of their full notes have been attached to the medical records of each patient so as to provide guidance for members of the house staff and members of the visiting staff as well. On various occasions during the course of the teaching session the members of the staff of the unit have presented the

*We were fortunate in obtaining the co-operation of Drs. Donald J. MacPherson, Laurence D. Streett, Frank L. d'Elia and John A. Abbott, all of whom are practicing psychiatrists with a strong interest in psychotherapy and an enthusiasm for individual instruction.

biographical material concerning patients who were presented at the weekly medical grand rounds attended by the students and visiting staff. These presentations have been effective in stimulating general interest in the psychologic problems of patients in the hospital. A psychiatric social worker was found to be indispensable. Although she has been able to make contact with various relevant social agencies, her more important function has been that of active participation in the handling of the more significant relatives of patients who are being treated by the physicians of the unit. It was found that a full-time secretary had all that she could do to keep up consultation notes and treatment interviews for the four members of the staff.

Future Planning

It has been found during the course of the past year that effective teaching of medical students and staff can be carried out only if those who are giving the instruction have a grasp of the case material used for illustration that is considerably more profound than a beginner could expect to achieve even after a series of interviews with the patient. To give students any help in handling their patients more effectively, those who are doing the teaching must have as clear a realization as possible of the nature and therapeutic plasticity of the patient's difficulties. This not only requires considerable maturity and experience but also can be carried out with conviction and vitality only if those who are doing the teaching of beginners are at the same time in daily therapeutic contact with patients at a much more understanding level than would be possible or desirable for a student. These considerations are of particular importance when any future expansion of the present program is considered. In other words, teaching of additional medical students, members of the medical house staff, members of the visiting staff and others could be carried out usefully only with the help of mature and experienced psychiatrists who would be interested. Unsupervised teaching by beginners is quite likely to do more harm than good.

These considerations seem to apply to the problem of research along psychologic lines in the general medical field. It is our conviction that the most needed type of research is in the field of therapy, which is also the chief avenue to an understanding of fundamental etiology. Although the collaboration of colleagues versed in the discipline of physiology and biochemistry is desirable, what is most needed in the personnel undertaking such research appears to be a thorough grounding in psychiatry and psychotherapy.

Cost

The unit has been housed at the Peter Bent Brigham Hospital, where office space has been assigned each member. Salaries and operating expenses amounted to \$17,000 during the first year of operation.

The distribution of salaries was according to the relative training and experience of the various members of the unit. The junior members of the staff were willing to serve for low salaries because of the opportunities for experience and teaching.

SUMMARY

An experimental medicopsychiatric teaching unit has been in operation on a one-hundred-bed medical service at the Peter Bent Brigham Hospital for a year.

Methods of psychologic treatment appropriate to the care of patients admitted to general hospital wards are discussed.

A program for the teaching of the emotional factors in general medical practice has been established for third-year and fourth-year medical students assigned to the Medical Service.

A course for medical house officers has been presented with seminar discussions and individually supervised clinical work.

Considerations relevant to expansion of the present service are discussed, with particular regard to the requirements and opportunities of the personnel.

PLEURODYNIA*

Preliminary Note on an Epidemic in Boston

JOHN J. FINN, JR., M.D.†

BOSTON

BEGINNING in July and continuing through August and September, 1947, a large group of patients afflicted with an acute febrile illness resembling what has been popularly known in the United States as "devil's grip" or "epidemic pleurodynia" were admitted to the medical and surgical wards of the Boston City Hospital. At the time of submission of this report, patients are still being admitted sporadically.

So far as is known, the last reported epidemic of this disease in the United States was the Brooklyn epidemic of 1942.¹ A smaller group of cases, consisting of 12 hospitalized and 8 nonhospitalized patients among members of the families of the hospital patients, were observed at the Boston City Hospital during the same year.²

The current epidemic appears to be of major proportions, for not only is the number of known hospitalized cases at the Boston City Hospital well over the 100 mark but also the number seen in the Outpatient Department and on the Emergency Floor and not admitted is estimated to have far exceeded this figure. Furthermore, the known nonhospitalized cases among members of the patients' families and friends, in addition to reports of cases seen at other hospitals in Boston and throughout New England, make it appear that the total number of cases of the disease must have numbered in the thousands.

If the experience at the Boston City Hospital is any criterion, it appears that the disease is being misdiagnosed in many cases and is being confused with pneumonia, influenza, infectious mononucleosis, nonparalytic poliomyelitis, lymphocytic choriomeningitis, gastroenteritis and acute surgical conditions of the abdomen. The diversity of signs and symptoms easily accounts for this confusion.

The purpose of this preliminary report is to call attention to the presence of the epidemic and its varied manifestations among the patients seen at the Boston City Hospital. The report includes a general description of the disease, with some of its less common manifestations, as well as selected case reports from the present epidemic, which will suffice to point out the diverse manifestations of this disease. The literature concerning this disease was reviewed in 1934 by Sylvester³ and in 1946 by Scadding.⁴

A complete report of the clinical data and laboratory studies of cases seen at the Boston City Hospital during the current epidemic and the one of 1942 will be presented at a later date.

DESCRIPTION

The disease occurs in the late summer and early fall and seems to affect mostly younger people. In general, it is characterized by lack of prodromes, the onset being sudden and the initial symptom in most cases being pain. The pain is usually located in the lower thoracic or upper abdominal regions, or both, and may vary in intensity from a dull ache or distressed tight feeling to an excruciating type. The pain is usually intimately associated with the line of attachment of the diaphragmatic insertions to the thoracic wall and is aggravated by deep breathing, by coughing and frequently by motion. There is usually an associated hyperesthesia in the areas of distribution of the pain, which tends to occur in paroxysms. It may shift from one side of the thorax to the other but is usually located in the region of the diaphragmatic attachments. Shoulder, scapular or interscapular reference of the pain may occur. Soon after or coincident with the onset of pain, there is fever, the temperature reaching as high as 104°F in a few hours (usually about twelve hours), with a gradual fall to normal within the next twelve hours. After the initial return of the temperature to normal, there may be one or more recrudescences of pain and other symptoms. Between recrudescences, the patient may be completely asymptomatic. Once the fever has permanently remitted there are usually no further symptoms except for an occasional twinge of pleurodynia. The fever, however, may run an irregular course up to ten to fourteen days. Chills or chilly sensations are not uncommon and may be the initial symptom. Other symptoms described in previous epidemics include mild upper respiratory symptoms, such as a so-called "head cold," mild pharyngitis and slight, nonproductive cough; central-nervous-system symptoms such as headache, which may be severe, photophobia, paresthesias and even convulsions, and gastrointestinal symptoms, such as anorexia, nausea, vomiting, diarrhea and tympanites, especially in children. Physical findings in the usual case are rather few other than the fever, splinting of the chest and upper abdominal or thoracic tenderness. A pleural friction rub may or may not be heard at

*From the First and Third Medical Services (Tufts) Boston City Hospital.

†Chief resident, Third Medical Service Boston City Hospital.

some time during the course of the disease or even in convalescence. X-ray films of the chest are classically completely normal. Laboratory studies are of little significance. The white-cell count is normal or slightly elevated at the beginning of the illness, with a drop later. Eosinophilia, especially in convalescence, has been described in earlier epidemics. The disease is apparently a benign one in the vast majority of cases, although complications such as pericarditis, orchitis and jaundice have been mentioned.

The cause of the disease is unknown, the general impression being that it is of viral origin with an incubation period of eight to ten days.

CASE REPORTS FROM THE CURRENT EPIDEMIC

The diversity of signs and symptoms of the disease as seen in the present epidemic is best illustrated by the following selected cases. The first illustrates the clinical course of a typical case and the high household incidence of the disease.

CASE 1 A 44-year-old man entered the hospital on July 28, 1947, because of chest pain, fever, vomiting and chilliness. He had been well until a few hours before admission, when he had noted chilly sensations, and shortly thereafter he had been seized with a sharp vise-like pain around the entire lower thorax. The pain was aggravated by respiration and radiated to both shoulders and to the interscapular region. In addition, the patient vomited and noted a "burning" sensation of both eyes.

Physical examination revealed slight conjunctival injection, a few nontender palpable cervical lymph nodes, splinting of the right half of the chest and tenderness to palpation over the lower thorax and upper abdomen bilaterally.

The temperature was 103.6°F, the pulse 112, and the respirations 40. The blood pressure was 110/70.

Examination of the urine, and cultures of the nose, throat and blood were negative. Examination of the blood disclosed a white-cell count of 17,600, with 80 per cent neutrophils and 20 per cent lymphocytes. The sedimentation rate was normal, as were an x-ray film of the chest and an electrocardiogram. The white-cell count fell to 6800, with an essentially normal differential count, on the 4th day, and on the 7th day it was 12,000, with 69 per cent neutrophils, 25 per cent lymphocytes and 6 per cent eosinophils. Treatment consisted of intramuscular penicillin and Demerol. Within 24 hours after admission the temperature had returned to normal, remaining so for 48 hours, when there was a recrudescence to 102°F and a return to normal within 24 hours, only to be followed 72 hours later by a final rise to 99.8°F. A pleural friction rub was heard over the right lower posterior portion of the chest on the 7th day, and on the 10th day it was heard bilaterally over the lower portion of the chest anteriorly and posteriorly, and was still present, although the patient was asymptomatic, when he was discharged on August 7.

Five other members of the patient's family and 3 people living in the tenement below became ill, with similar symptoms, either a few days before or a few days after the patient's illness had begun.

The following case illustrates the central-nervous-system involvement and a rather common hematologic picture.

CASE 2 A 21-year-old woman entered the hospital on July 29, 1947. She had had a mild diarrhea 4 days prior to entry, and on the following day awoke with a severe pain in the upper epigastrium, radiating to the neck and ears and aggravated by respiration. The pain was accompanied by malaise, fever, chilly sensations and severe headache. For the next 3 days there were daily recurrences of all symptoms,

and the pain became localized first to the left lower lateral portion of the chest and then to the right lower lateral portion, and was referred to the right shoulder and scapular area.

Physical examination showed a somewhat drowsy patient, with slight pharyngeal injection, a few palpable axillary and inguinal lymph nodes, moderate tenderness to palpation over the lower part of the sternum, right lower lateral portion of the chest and right costovertebral region and tenderness to deep pressure in both calves.

The temperature was 103.8°F, the pulse 104, and the respirations 24.

Cultures of the blood, throat and feces and examination of the urine were negative. Examination of the blood revealed a white-cell count of 3600, with 57 per cent neutrophils, 41 per cent lymphocytes, 4 per cent monocytes, 1 per cent basophils and 8 per cent atypical lymphocytes. X-ray films of the chest and an electrocardiogram were normal. On the 8th day the white-cell count was 7300, with 55 per cent neutrophils, 32 per cent lymphocytes, 2 per cent monocytes, 3 per cent eosinophils and 8 per cent atypical lymphocytes. Heterophil-antibody agglutinations done on the 1st, 4th and 7th hospital days were all negative. The spinal fluid on admission showed 22 white cells per cubic millimeter, of which 18 were lymphocytes, 2 were neutrophils and 2 were monocytes. Culture of the spinal fluid showed no growth, and the chemical and serologic findings were normal.

The patient received intramuscular penicillin therapy during the first few hospital days. Within 24 hours after admission, the temperature had dropped to normal only to rise again to 104°F 12 hours later. There were two subsequent temperature rises to 102 and 103°F, respectively, at approximately 24-hour intervals. By the 5th hospital day the patient was afebrile and remained so. During the first few hospital days a moderate enlargement of the axillary and inguinal lymph nodes was noted, but the spleen and liver did not become enlarged. A pleural friction rub, first heard in the posterior axillary line of the right lower portion of the chest on the 5th hospital day, was still present when the patient was discharged asymptomatic on August 7.

The last case illustrates the possible confusion of the disease with acute surgical conditions of the abdomen.

CASE 3 An 11-year-old boy was admitted to the hospital on September 7, 1947. Three days prior to entry he had noticed the sudden onset of periumbilical pain and a temperature of 101°F. Within a few hours all symptoms disappeared until the day of entry, when once again there was a recurrence of the fever and of the pain, which was aggravated by respiration and felt also in the left lower anterior portion of the chest and in the anterior part of the neck just below the thyroid cartilage.

Physical examination revealed rapid and shallow breathing, with obvious splinting of the chest and abdomen. A questionable pleural friction rub was heard in the right lower lateral portion of the chest, and there were slight tenderness and spasm in the upper abdomen.

The temperature was 102.4°F and the pulse 80. Examination of the urine, a blood culture and heterophil-antibody tests were negative. Examination of the blood disclosed a white-cell count of 13,150. The sedimentation rate, an x-ray film of the chest and an electrocardiogram were normal. On the next day the white-cell count was 3800, with 38 per cent neutrophils, 4 per cent monocytes, 1 per cent basophils, 1 per cent eosinophils and 52 per cent lymphocytes, many of which were immature.

The patient had been admitted to a surgical ward for surgical observation, but operation was not performed. Within 24 hours after admission, the temperature had dropped to normal, and the patient had become completely asymptomatic and remained so. About 72 hours after admission, however, the temperature rose to 100.5°F but rapidly returned to normal, where it remained. He was discharged asymptomatic on August 13.

At follow-up study on August 22 physical examination was negative, and blood studies showed a normal sedimentation rate, a negative heterophil-antibody test and a white cell

count of 9050, with 57 per cent neutrophils, 34 per cent lymphocytes and 8 per cent eosinophils. The patient's mother stated that a younger brother had become ill with similar symptoms the day after the patient had been admitted to the hospital.

SUMMARY

An epidemic of "devil's grip" or "epidemic pleurodynia" occurring in Boston during July, August and September, 1947, is reported.

The epidemic appears to have been of major proportion throughout Boston and elsewhere in New England, with over 100 cases admitted to the Boston City Hospital alone.

A general description of the disease and some of its diverse manifestations is presented, and three selected, illustrative case reports from the current epidemic are submitted.

MEDICAL PROGRESS

NEUROLOGY

H. HOUSTON MERRITT, M.D.,* AND WILLIAM KING JORDAN, M.D.†

NEW YORK CITY

PHYSIOLOGIC studies of significance in 1946 include the reports on the effect of di-iso-propyl-fluorophosphate on transmission of the nerve impulse and the effect of this compound on the symptoms of myasthenia gravis. The poor results obtained with the use of di-iso-propyl-fluorophosphate in patients with myasthenia gravis, although there was a great decrease in plasma cholinesterase, suggest that the therapeutic effect of neostigmine in this disease is not related to its effect on the cholinesterase.

Important clinical studies were made on diseases of the cerebral blood vessels, the measurement of sympathetic activity in nerve injuries by the dermometer and the treatment of infections of the nervous system with streptomycin and penicillin. Several reports indicate that streptomycin is highly effective in the treatment of meningitis caused by *Haemophilus influenzae*. It has a definite effect on the course of tuberculous meningitis, prolonging life without effecting a cure in the majority of cases in which it has been used. Further reports on the results obtained with the use of penicillin in the therapy of neurosyphilis suggest that this antibiotic will ultimately replace the older, laborious and more dangerous forms of therapy in this disease.

The studies mentioned above, together with numerous others, are considered under the following headings: physiology, cerebral blood vessels, nerve injuries and skin-resistance tests, infections, convulsive disorders, and miscellaneous considerations.

PHYSIOLOGY

In the course of chemical-warfare research, it was found that di-iso-propyl-fluorophosphate (DFP) seemed to act as an "irreversible" inhibitor of cholinesterase and thus apparently to set up the possibility of a direct, crucial test of the importance of the acetylcholine system to propagation of nerve impulses. Crescetti, Koelle and Gilman,¹ in experiments with the sciatic nerve of bullfrogs, found that the action potential was abolished by the application of DFP but reappeared on removal of the nerve from the compound. After the injection of frogs with DFP, only traces of cholinesterase activity were found in the excised nerves, which nevertheless had conduction properties similar to those of control fibers. From these experiments, it was concluded that there is no parallel between the magnitude of the action potential and the cholinesterase activity.

Nachmansohn and his collaborators²⁻⁴ have criticized certain technical aspects, as well as the conclusions, of this work, offering several experiments in rebuttal. In manometric studies with cholinesterase and by experiments on lobsters and squid nerve, these workers have shown that the inhibiting action of DFP is not immediately irreversible, but that the irreversibility of the action depends on the time of exposure of the enzyme to the drug and on the temperature. The time independence of the inactivation was used to demonstrate that progressive irreversible depression of the action potential was paralleled by a progressive decrease in available cholinesterase. Similarly, it was found that com-

*Professor of clinical neurology, College of Physicians and Surgeons, Columbia University; chief of Division of Neuropsychiatry, Montefiore Hospital.

†Research associate, Division of Physiology, Princeton University.

plete return of the action potential in these nerves is always accompanied by the presence of at least 20 per cent of the initial cholinesterase

In evaluating these and similar experiments, Grundfest⁶ came to the following conclusion "Whatever its specific role may be, the acetylcholine system enters into the activity of excitable conductile tissue at a more crucial stage than do, for example, oxygen and other metabolic systems"

Two studies have appeared on the effects of DFP in normal subjects and in patients with myasthenia gravis. Comroe and his associates⁷ found a marked reduction in plasma cholinesterase activity and a slight reduction of red-cell cholinesterase in normal persons after the administration of DFP in doses of 0.7 to 3.0 mg intramuscularly and 2.5 to 10.0 mg orally. Single intramuscular injections in normal subjects had no effect on pulse, blood pressure, electrocardiogram, vital capacity or blood sugars. In 7 patients with myasthenia gravis comparison was made of the effectiveness of DFP with that of neostigmine in the relief of weakness and in the correction of abnormal electromyogram characteristics. DFP, in doses of 2.5 to 210 mg given over periods of one to one hundred and fifty days, was longer lasting in its effect than neostigmine but did not produce so great an increase in strength. DFP decreased plasma cholinesterase activity to 1 to 10 per cent of normal, with only partial improvement of strength, whereas neostigmine produced marked increase of strength with decrease of plasma cholinesterase activity to only 50 to 70 per cent of normal. Thus, it appears that the efficiency of drugs in the treatment of myasthenia gravis cannot be determined by their effects on plasma cholinesterase. Toxic symptoms that result from the use of this compound include anxiety and disturbing dreams, and abnormalities may develop in the electroencephalogram.

In a second series of observations, Harvey et al.⁸ compared the results of the injection of 1.5 mg of DFP in physiologic saline solution into the brachial arteries of normal and myasthenic subjects. In the former, fasciculations and weakness developed in the muscles supplied by this artery, whereas in the latter there were no fasciculations and there was an increase in strength of eight to ten days' duration in muscles supplied by the artery, with restoration of normal electromyographs.

It was a dictum of Hughlings Jackson that movements, not muscles, are represented in the motor cortex, whereas Sherrington developed a theory of punctate localization of cortical motor function. Hsiang-Tung Chang, Ruch and Ward,⁹ in the light of these differing views, have investigated the topographic representation in the motor cortex of individual muscles acting over the ankle joint of macaque monkeys. Not only individual muscles but also slips of muscles were found to have a focal point in the cortex from which an isolated response of that muscle or muscle slip is elicitable or at which the re-

sponse is stronger and prompter, in relation to other muscles.

Lloyd¹⁰ has continued his studies of the functional organization of the spinal cord with an investigation of events at the synapse in a 2-neuron arc. He finds evidence that three events take place at the synapse. The first is a brief, powerful component of the excitatory event, capable of adequate stimulation of the neuron and already well known as the "detonator action." The second is another component of excitation of longer duration than the first, not so powerful, capable of facilitating the "detonator action," but not in itself capable of discharging a neuron, Lloyd calls this "residual facilitation." The third event, an inhibitory process, is considered the functional opposite of "residual facilitation," on the basis of its characteristics of temporal delay. In a broader study Lloyd¹¹ investigated the relation of these phenomena to the integrative pattern of the spinal cord and showed that without the necessity of other than direct reflex connections, the myotatic unit exhibits, complete within itself, the elementary mechanism of reciprocal innervation.

Lennox and Ruch¹² have developed a technic in monkeys for recording the electrical activity of the brain by means of wire electrodes inserted into the ventricles. They have suggested that the method is applicable to human beings in conjunction with ventriculography and believe that by its use, it may be possible to lateralize deep subcortical lesions and to demonstrate the subcortical origin of various abnormal waves.

CEREBRAL BLOOD VESSELS

Kubik and Adams¹³ have analyzed the clinical and pathological manifestations in 18 cases of occlusion of the basilar artery. This finding has been observed at autopsy in 1,300 cases at the Massachusetts General Hospital and the Mallory Institute of Pathology. The occlusion was thrombotic in 11 of 18 cases, and embolic in the remaining 7. The symptoms and signs were found to fit a rather definite pattern, characterized by abrupt onset and changes in state of consciousness varying from confusion to coma, with headaches, dysarthria and dysphagia, pupillary abnormalities, ocular and facial palsies, hemiplegia or quadriplegias, bilateral extensor plantar responses and often a terminal hyperpyrexia. In some cases there was a temporary remission, followed in fatal cases by relapse and death. The cerebrospinal fluid was clear and under normal pressure. The authors also state that they have seen 7 patients who recovered after the occurrence of signs and symptoms resembling those of basilar-artery occlusion.

Madonick, Savitsky and Hochfeld¹⁴ reported a patient dying with a subarachnoid hemorrhage from an intracranial aneurysm associated with polycystic kidneys in whom these findings were verified at necropsy. They described another patient who had

two episodes of subarachnoid bleeding and in whom intravenous urography revealed signs of polycystic kidneys. They also found in the literature 13 cases of verified intracranial aneurysm accompanied by polycystic kidneys.

A series of 15 patients in whom vascular anomalies of the cerebral cortex were present in association with Jacksonian epilepsy has been reported by Reichert.¹⁴ Surgical treatment, consisting in coagulations of the vascular lesions, resulted in the disappearance of attacks in 6 cases, milder and less frequent seizures in 7 and no improvement in 2.

Kilbourne and Wolff¹⁵ have studied 21 cases of temporal arteritis, which they conclude is a well defined pathologic entity. It characteristically occurs in patients of both sexes between the ages of fifty-five and eighty, with painful inflammation of one or both temporal arteries as the main symptom. Usually present are the findings of a mild systemic infection, with leukocytosis but without eosinophilia. Koch's postulates have not been fulfilled for any causative organism, and the authors discuss the possibility of an allergic etiology. Ocular symptoms appeared in 7 cases, ranging from photophobia and diplopia to blindness. Four patients showed lethargy and mental retardation suggestive of encephalitis. Complete recovery took place in all patients within two to twenty months, except for blindness, which persisted when it occurred, and except for a patient who remained mentally retarded. Pathological findings in temporal-artery biopsies are indistinguishable from those of periarthritis nodosa, but the authors point out that the nonfatal course and absence of visceral involvement in temporal arteritis serve to differentiate it from periarthritis nodosa. Because of signs of involvement in many cranial arterial branches in this disease, it is suggested that it be called "cranial arteritis."

In a review of experience with cerebral angiography by means of thorium dioxide at the University of Pennsylvania Hospital, Govons and Grant¹⁷ state that they have found the procedure of value in the localization of intracranial aneurysms, angiomatous malformations of the brain, occlusions of the internal carotid artery and traumatic arteriovenous aneurysms. They believe that pneumoencephalography is still the mechanical technique of choice for the localization of cerebral neoplasms.

NERVE INJURIES AND SKIN-RESISTANCE TESTS

Richter¹⁸ has summarized information concerning the use of his dermatometer — a device that measures the relative electrical resistance of the skin. The model he has introduced consists of a microammeter, potential divider, $4\frac{1}{2}$ volt battery, and two electrodes, one indifferent for attachment to the ear, and the other for exploration. This instrument affords a relative, but not quantitative, measure of skin resistance. Resistance to the passage of a minute direct current, imperceptible to the subject,

is localized to the skin, and is controlled largely through sympathetic fibers that govern the activity of sweat glands. The activity of these glands, in turn, determines to a first approximation the degree of skin resistance. Under ordinary conditions normally innervated skin shows distinct regions where resistance is high, and others where it is low. In general, areas of low resistance are found when there is a rich sweat-gland supply, such as the palms of the hands, the soles of the feet, the center part of the face, the axillae and the antecubital fossae. Section of a nerve trunk or removal of sympathetic supply to an area by ganglionectomy markedly increases skin resistance in the area supplied by these structures. Stimulation or irritation, on the other hand, of nerve or sympathetic chain decreases resistance. Transection of the cord at the first thoracic segment, above the thoracolumbar outflow, increases skin resistance over the head, trunk and extremities. Transection at the second lumbar segment, below the outflow, has no effect on resistance, whereas that within the outflow increases resistance of the skin supplied by the spinal-cord segments below the lesion.

The dermatometer has proved useful in the diagnosis of peripheral-nerve injury, particularly in distinguishing between complete and partial sections, in determining the earliest signs of regeneration of sympathetic fibers, in determining the rate of regeneration of sympathetic fibers with relation to sensory and motor fiber regeneration, in studying the distribution of the sympathetic component of each of the peripheral nerves separately and in combination and in ascertaining actual nerve injury in suspected cases of malingering.^{18, 19} It has also been valuable as an aid in the diagnosis of injury or irritation to the sympathetic system, as in brachial-plexus pressure, as well as in mapping areas of skin denervation by sympathectomy, or procaine paravertebral blocks of sympathetic nerves, and finally as a help in the localizing of the level of injury to the spinal cord or roots.

Several papers have described the value of sympathectomy in the treatment of causalgia. Ulmer and Mayfield,²⁰ in a review of 72 cases of causalgia due to war wounds of large mixed peripheral nerves, state that 63 of 70 patients were relieved of pain by the first operation consisting of sympathectomy in appropriate areas of the sympathetic chain. Two patients were successfully treated by resection of the injured nerve segment.

Rasmussen and Freedman²¹ report relief of pain in 28 of 35 cases by surgical sympathectomy for causalgia of the arm, with less satisfactory results for causalgia of the leg. Similarly, White²² has reported success with this type of procedure in treatment of causalgia.

Schlesinger²³ has described the use of a suspension of eucaine in oil and wax for the relaxation of spasticity following injury of the spinal cord. With

doses of 10 to 15 cc of curarine in oil, he found that relaxation occurred lasting as long as three days, without concomitant appearance of undesirable side effects. The emergence of voluntary function apparently masked by spasticity and the relaxation of muscle spasm, thus permitting physiotherapeutic procedures to be instituted, seemed to be of value in 11 patients treated in this manner.

INFECTIONS

A number of reports have appeared on the use of streptomycin in infections of the nervous system due to gram-negative and acid-fast organisms.

In a comprehensive paper on the use of streptomycin, the Committee on Chemotherapeutics of the National Research Council²⁴ reports 100 cases of meningitis caused by *H. influenzae* and treated with this drug. Of these, 66 patients were cured clinically and bacteriologically while under treatment, 13 improved and finally recovered, 1 improved but relapsed, 3 showed no effect, and 17 died. Only 18 patients were treated by streptomycin alone. Analysis of the 17 fatal cases demonstrated that the factor most unfavorable for streptomycin treatment is late use of the drug after other forms of therapy have failed. In this connection, the report calls attention to the favorable results reported by Weinstein,²⁵ which suggest that early diagnosis and prompt intramuscular and intrathecal injection of streptomycin are usually followed by prompt improvement. Weinstein also stresses the occurrence of superinfections due to other organisms, such as the staphylococcus, that are resistant to streptomycin but may be sensitive to penicillin.

Although more streptomycin is present in the cerebrospinal fluid of patients with meningitis than the small amount appearing in the spinal fluid of non-meningitic patients after parenteral administration of the drug, the Council recommends intrathecal as well as intramuscular routes of dosage in meningitis therapy. The average daily dose given to the patients in the series who recovered was 0.5 gm intramuscularly, and 0.060 gm in 5 to 10 cc of physiologic saline solution intrathecally, for nine and seven days respectively.

The Council also reports a group of 14 cases of meningitis caused by gram-negative organism other than *H. influenzae* but concludes that the series is too small for satisfactory analysis.

Alexander and her associates,²⁶ after treating 25 patients with influenzal meningitis with streptomycin alone or along with other agents, state that streptomycin therapy alone will bring about recovery when the meningitis is of average severity, but that when the infection is unusually severe, therapeutic failure will probably be reduced to a minimum by the initial use of rabbit antiserum, sulfadiazine and streptomycin.

Hinshaw, Feldman and Pfuetze²⁷ describe 11 patients with milary tuberculosis and tuberculous in-

volvement of the central nervous system treated with streptomycin. Four of 9 patients so treated, who had tuberculous meningitis as proved by the clinical picture, spinal-fluid abnormalities and demonstration of the tubercle bacillus, have survived for five to ten months, although the cerebrospinal-fluid abnormalities persisted. The authors also emphasize the value of both intrathecal and intramuscular administration of the drug, stating that in their series no patient who has had intrathecal as well as intramuscular therapy has died of tuberculous meningitis.

More information on the use of penicillin in the treatment of neurosyphilis is available. Stokes and Steiger²⁸ have described the results of penicillin alone in 283 patients with neurosyphilis. The routes of administration and dosage varied widely, and many of the patients were treated during the period of high variability of potency of penicillin supplies. They recommend at present a course of not less than 4,800,000 units in not less than seven and a half days, around the clock, penicillin being used in physiologic saline solution intramuscularly. Improvement in the spinal fluid was found in 62 per cent of patients with dementia paralytica, 57 per cent with tabes dorsalis, 60 per cent with asymptomatic involvement and 63 per cent with congenital syphilis. Clinical improvement was claimed for 30 per cent of patients with dementia paralytica, 31 per cent with tabes dorsalis and 17 per cent with meningovascular neurosyphilis. The results with primary optic atrophy were considered inconclusive.

Jones and Perk²⁹ report 6 cases of dementia paralytica treated with two courses of 2,400,000 units of penicillin separated by a month. Three patients were considered improved clinically, 1 was unchanged, and 2 became progressively worse. In all cases there was improvement in the spinal fluid, a reduction in the cell count usually occurring first.

Nelson and Moore³⁰ have reported the results of an additional year of observation of 10 patients treated with penicillin for acute syphilitic meningitis and previously reported. In all 10 cases the spinal-fluid reaction, originally strongly positive, has become negative. Because of the excellent results with penicillin given intramuscularly in this form of neurosyphilis, the authors believe that it is not necessary to give penicillin intrathecally in treatment.

Callaway and his associates³¹ have treated 2 cases of syphilitic arachnoiditis with subarachnoid block by 4,000,000 units of penicillin intramuscularly and intrathecally, and report improvement as occurring in contrast with unfavorable results with other modes of therapy.

Reports on toxicity of antibiotics for the central nervous system have appeared. Brown and Hinshaw³² have reported dizziness, tinnitus and even loss of hearing as occurring in patients treated for

tuberculosis in large doses over long periods with streptomycin

Johnson et al.³³ investigated the effects of several antibiotics on the nervous system. Both penicillin and streptomycin produced convulsions when applied directly to the cerebral cortex. Although a fairly wide margin of safety was observed between the effective antibiotic concentrations and the convulsive concentration, the authors warn against direct exposure of the nervous system to excessive dosage of the drugs. During systemic administration of penicillin for non-neural disease, 60 per cent of patients were found to have abnormal encephalograms.

Sachs,³⁴ in a review of his experience with 142 cases of brain abscess seen during the past thirty years, concludes that no unencapsulated abscess should be drained, that penicillin during the acute stage is an invaluable aid in bringing about encapsulation, that aspiration, except in cerebellar cases, should be used only as a palliative procedure until more radical treatment can be instituted and, finally, that excision without drainage is the ideal procedure.

Five cases of radical total dissection of brain abscesses, aided by sulfonamide and penicillin therapy, have been reported by Fincher.³⁵ He states that his results with this method suggest that the basic surgical principle of "incision and drainage" in the treatment of certain abscesses of the brain can be replaced by total dissection of the abscess and primary closure of the wound.

Bronson³⁶ has reviewed a neurologic syndrome occurring among members of the armed forces that was characterized by varying degrees of disturbance ranging from mild peripheral neuritis to severe debility "involving the central nervous system as well as the peripheral nerves, similar to the Guillain-Barré syndrome." Out of 60 such patients at an Army hospital, the syndrome was found to follow cutaneous diphtheria in 5, faucial diphtheria in 2 and a severe sore throat thought to be diphtheritic in 5 others. In the remaining 48 cases, as well as in 13 patients with a similar syndrome in Australia, there was no evidence of diphtheritic involvement.

Gaskill and Korb³⁷ have described a small epidemic of cutaneous diphtheria striking 140 patients, in 61 of whom multiple neuritis developed. The authors found evidence in their study that early administration of diphtheria antitoxin in adequate doses significantly reduces the incidence of this complication.

Involvement of the central nervous system in Asiatic schistosomiasis has been reviewed by Cutter.³⁸ This frequently manifests itself with the symptoms of a space-occupying brain or cord lesion. The importance of early treatment is emphasized by the author.

Winkenwerder and his associates³⁹ have reported a series of 364 cases of Asiatic schistosomiasis, emphasizing particularly the value of Fuadin, an anti-mony-containing compound, in the treatment of this condition.

CONVULSIVE DISORDERS

In a study of biochemical changes induced by convulsant drugs in the cortex of the cat, Klein and Olsen⁴⁰ observed decreased concentrations of brain glycogen, glucose, phosphocreatine and adenosine triphosphate as a result of convulsive activity, whereas there were increased concentrations of lactate, adenosine diphosphate and inorganic phosphate. They conclude that the cerebral metabolism of glucose is markedly increased during convulsive activity.

Perlstein and Andelman⁴¹ have reported on the use of tridione in convulsive and other disorders. They found dramatic improvement in 6 of 7 patients with petit-mal epilepsy after the administration of the drug. Tridione afforded marked benefit in 3 patients with psychomotor attacks. Results in patients with grand-mal seizures were disappointing. The authors also gave tridione to patients with cerebral palsies and stated that it is of value in reducing tension or rigidity. It was found to be of no particular benefit in chorea, Parkinsonism or dystonia musculorum deformans.

Two fatal cases have been described in patients given anticonvulsant therapy that included tridione. Harrison, Johnson and Ayer⁴² reported that a sixteen-year-old girl died from aplastic anemia after having taken tridione and methylphenylethylhydantoin concurrently for six months. Mackay and Gottstein⁴³ described the case of a twenty-four-year-old man who developed an acute aplastic anemia resulting fatally after taking tridione and phenobarbital for ten months.

Robinson⁴⁴ has presented the results of repetition of electroencephalography in adult patients with epilepsy. In 140 patients, of whom 100 had no demonstrable abnormalities and 40 had various types of lesions, the electroencephalogram was repeated after an interval of five to seven years, no essential change in the patients' anticonvulsant therapy having occurred during that time. Among the group without central-nervous-system disease, the electroencephalogram pattern was the same in 85 per cent, worse in 10 per cent and better in 5 per cent. In patients with associated lesions the electroencephalographic tracing was the same in 95 per cent, worse in 2.5 per cent and better in 2.5 per cent. Since the incidence of abnormality could be lowered only in cases in which subsequent electroencephalograms showed improvement, it was evident that the chance of such a decrease was only 5 per cent in the first group and only 2.5 per cent in the second. Thus, a single electroencephalogram taken at any given time has a 95 to 97.5 per cent likelihood

of representing the true electroencephalographic nonconvulsive state of an epileptic adult under unchanging therapy

MISCELLANEOUS CONSIDERATIONS

The history of a soldier who for ten years had symptoms of narcolepsy, cataplexy and trance-like catalepsy has been reviewed by Fabing⁴⁵. The condition of the patient was unrecognized, and he went through the Tunisian and Sicilian campaigns of World War II, having repeated attacks during combat. On the basis of analysis of this man, the author elaborates a theory of the pathogenesis of narcolepsy, holding that the fundamental pathophysiologic cause of the disorder is an abnormal susceptibility to inhibition in the brain of the patient.

Two studies have appeared on the rapid production of acute disseminated encephalomyelitis in Rhesus monkeys by the injection of emulsions of brain tissue with dead tubercle bacilli added as an adjuvant. Kabat, Wolf and Bezer⁴⁶ produced multiple lesions in such animals in fifteen to thirty days with three injections of emulsions containing either normal rabbit or monkey brain with killed dried tubercle bacilli added as an adjuvant. In previous investigations that did not use adjuvants, thirty to one hundred injections of brain tissue were found to produce similar lesions in three to thirteen months. It was observed that emulsions of fetal rabbit brain (containing no myelin) and emulsions of adult rabbit lung in addition to adjuvants did not induce disease. These investigators believe that the lesions essentially resemble those of acute disseminated encephalomyelitis in human patients. Morgan⁴⁷ using similar techniques, arrived at similar results. Particularly interesting are her observations that peripheral-nerve emulsions do not produce these lesions.

Ferraro, Roizin and Hilfand⁴⁸ have studied the histologic response of monkey-brain tissue to electric currents similar in type, intensity, duration of flow and frequency to those used in human electric-shock therapy. Pathologic changes were most pronounced in areas of tissue traversed by the main path of the current and, when present, consisted of nerve-cell alterations mostly of the reversible type and distention of perivascular spaces, with perivascular edema, diapedesis of formed blood elements and gutter cells filled with what was presumably hematic pigment. With more intense and longer current flow, occasional petechial hemorrhages resulted. This was considered by the authors to support the thesis that the severity of lesions is proportional to the intensity and duration of the current flow and, to a lesser extent, to the number of shocks given.

Meyer⁴⁹ reported that folic acid in daily doses of 15 to 50 mg orally or 20 mg intramuscularly failed to prevent the progression of neurologic symptoms indicative of subacute combined sclerosis in patients with pernicious anemia. With combined liver ex-

tract and folic acid therapy, there was evidence of improvement in signs and symptoms of combined system disease.

Freeman⁵⁰ has described 4 cases of amyotonia congenita, or Oppenheimer disease, in which symptoms characteristically appear in infants and consist in paucity of movements, flabby muscles and weak cry. There is a possibility of persistence of life for a number of years, with slight improvement, although most patients with this disease die before the age of eighteen months. Pathologically, Freeman found almost complete absence of large multipolar cells of Betz in the precentral gyrus, together with a great reduction in number of anterior-horn cells at all levels, and a moderate degree of deficiency of multipolar cells in the motor nuclei of the fifth, seventh and tenth but not in the third or eleventh cranial nerves. He suggests the absence of Betz cells as an important point in the pathological differentiation of this disease from infantile spinal muscular atrophy. Freeman also mentions a woman, six of whose children had had amyotonia congenita, who was eventually able to decide whether or not a new baby would have the disease before its birth from the vigor of movements in utero.

The cerebral cortex in the very old human brain has been described by Riese⁵¹. The brains of 18 inmates of state institutions dying from the ages of seventy-seven to one hundred and seven were studied. A diagnosis of senile dementia had been made in 13 patients, psychosis with cerebral arteriosclerosis in 4 and involutional melancholia in 1. Most of the brains showed some degree of cortical atrophy, diffuse or regional, this feature showing no correlation with the age of the patient or the duration of the disease. The cytoarchitecture was found to be well preserved in all brains. All changes of all types were present, with liquefaction, shrinking and pigmentation most frequent. There was again no correlation with age or duration of illness, and the author was able to establish no connection between the diagnosis and the pathologic findings.

Clarke and Sneddon⁵² have reported neurologic findings in a group of 200 internees in Hong-Kong held prisoner from December, 1941, to September, 1945. During that time the internees subsisted on a diet consisting essentially of polished, deteriorating rice, 2 ounces of dried fish daily and occasional additions of beans and green vegetables (usually chrysanthemum leaves). Seventy-four prisoners showed neurologic symptoms, various combinations of optic atrophy, ataxic paraplegia and nerve deafness. At the end of two months of intensive treatment with high-calorie diets, massive vitamin therapy and liver extract, the neurologic symptoms showed no definite improvement.

Thorne and Eder⁵³ described 5 patients with chronic myopathy associated with thyrotoxicosis. Two of the patients had myasthenia gravis, which

the authors state is only rarely seen accompanying thyrotoxicosis

NEW HAMPSHIRE MEDICAL SOCIETY

PROCEEDINGS OF THE ONE HUNDRED AND FIFTY-SIXTH
ANNIVERSARY (Concluded)

House of Delegates, June 18, 19 and 20, 1947

The report of the Committee on Mental Hygiene was then presented as follows

The secretary, Dr Metcalf, has requested that this committee formulate a plan for mental-hygiene clinics, which we prefer to call a survey

Some years ago, through the interest of Dr Dolloff in mental-hygiene work, clinics were established whose purpose was to have persons who had been mentally ill and patients at the state hospital report for follow-up work and assistance in readjusting themselves in the communities to which they had returned. Out of this, clinics soon grew to take care of persons who did not need treatment in the hospital but who needed advice and help because of their emotional difficulties, finally, it became obvious that a full-time director was needed, to establish a series of clinics throughout the state. Dr Anna L. Philbrook, because of her training in psychiatry and in mental-hygiene clinic work and because of her personality, was chosen as director, and this has proved to be a wise appointment.

By her efforts a corps of personnel was formed that at the present time is not capable of fulfilling all the pressure of work put on it and has had to be assisted, through the kindness of Dr Dolloff, by three physicians on the staff of the state hospital: Drs Lombard, Hoyt and Nothmann, Dr Rabin, the director of the psychology department has also given assistance. The work has increased, owing to the facts that so many social agencies are referring cases to the clinics and that, more recently, clinics such as the orthopedic, tuberculosis and pediatric clinics are referring patients for study of personality make-up and emotional status so that they can be trained and rehabilitated to conform better with their type of physical handicaps. It is recommended that the personnel under the director be increased to include a full-time psychiatrist trained in mental-hygiene work, a full-time psychologist and a social worker. These three will prove of invaluable aid in assisting in the work. To acquire this personnel it is obvious that an appropriation of sufficient funds must be made by the state to carry on, and this amount should be \$20,000.

A large percentage of the patients seen have undoubtedly been saved from the development of a psychosis in later years, and from this point of view it can easily be shown that a saving of a considerable amount of money has been made for the state, because the cost of buildings sufficient to care for and treat the mentally ill would, at present, amount to about \$2300 a bed.

Another fact that has been brought out is that a number of children seen in the clinics have been found to have a severe neurosis and to need treatment in a residential setting, where more intensive psychotherapy and treatment could be carried out, and therefore we recommend a home for study and treatment of these children, preferably located on the state-hospital grounds or in close proximity to the grounds so that medical and other facilities of the Hospital can be used to full advantage. At present, the only residential setting for these children in New Hampshire is at the state hospital, where they have to be with adults, which is unfavorable to the children.

Another factor brought out was the rather uneven distribution of the work done in these clinics, which at present cannot be entirely avoided because of the lack of personnel, again showing the necessity for an increase. In Concord, Manchester and Nashua respectively, 124, 68 and 68 clinics were held, whereas in Laconia, Dover, Rochester and Conway respectively, 14, 9, 8 and 1 clinics were held. To be sure, the more thickly populated area of the state is in the southern part, but the north country and the

Connecticut River Valley should receive more attention proportionately than they have been able so far to be given. Owing to the pressure of the larger areas and to lack of personnel, it has been impossible to carry this out as desired.

The total number of visits to these clinics from July 1, 1944, to July 1, 1946, was 4400. One hundred and twelve mental-hygiene talks and classes were given by the clinic director, in addition to these clinics, and 109 staff conferences were held, showing the magnitude of the work that the director has been giving the clinics.

As a result of these clinics one fact that can be evaluated is that the present law limiting the age at which mental defectives can be institutionalized at the Laconia State School should be changed, so that children under five could be sent there if necessary.

Another factor that the committee believed that the State should consider was the employment of the services of a psychiatrist, interested in problems of delinquency, who could assist the courts and probation departments and could also attend to the psychiatric needs of the Industrial School and State Prison.

Another point brought to light was that the percentage of patients suffering from chronic alcoholism is on the increase in the state and that the admission of such patients to the state hospital has definitely increased, the state should begin to treat these patients as mentally ill, for most of them show either neurotic, psychopathic or schizoid traits, and alcohol serves as an escape mechanism. Referring these patients to mental-hygiene clinics could be one of the steps taken to help these patients to rehabilitate themselves without the necessity of committing them to the state hospital, which is already overcrowded.

In conclusion, the committee believes that the value of these clinics and the importance of expanding the Mental Hygiene Clinic system cannot be overstressed, and it is hoped that these recommendations will be referred to the Committee on Legislation for appropriate action.

A. B. HOWARD

Dr Macmillan stated that the Committee on Officers' Reports recommended the adoption of the report of the Committee on Mental Hygiene.

This motion was duly seconded.

The Speaker inquired whether the motion included the question of referral of the recommendations.

Dr Macmillan replied in the affirmative.

Dr Brody referred to several cases of children under five years of age who were mentally deficient and who could not be kept at home, according to the recommendations of the Child Mental Clinic, but who could not be placed. He considered the recommendation for admission to be one of the most valuable things that the Society could do.

Dr Macmillan asked what the age limit was.

Dr Brody answered that it was five years.

The Speaker then requested all those in favor of the motion to signify assent.

There was a chorus of "ayes," and the motion was carried.

The Committee on National Emergency Medical Service was presented by the chairman, Dr Daniel J. Sullivan, as follows

It is the considered judgment of the committee that the recruitment of the medical personnel for World War II was performed in a fairly satisfactory manner. The organization and operation of the Procurement and Assignment Service functioned well enough to carry out its mission namely to obtain sufficient medical personnel for the armed forces. It was slow in getting started however. In the event of another national emergency it might be well to have a permanent procurement board consisting of representative members of the American Medical Association and the surgeon generals' staffs already functioning. This general board could then determine age-group quotas for communities and formulate policies for local boards to follow. It is recommended that local boards of doctors be used for procurement and assignment rather than the placing of all the responsibility of procurement on one man in any given community.

In general the medical departments of the armed forces did an excellent job. It is believed that military personnel had sufficient medical care at all times. The quality and character of the medical service to military personnel has been lauded repeatedly. There has been adverse criticism regarding the utilization of medical personnel in the armed forces. In 1941 and early 1942 the flow of doctors into the Army and Navy was not constant nor was it in direct ratio to the size of the rapidly expanding forces. Later in 1942, when the Procurement and Assignment Service reached the peak of its activity, physicians arrived in the service in such large numbers that they were inevitably placed in medical pools awaiting military assignment. In these pools there were sometimes large numbers of doctors with not enough work to keep them busy. It is submitted that if a permanent procurement board were to exist the flow of doctors into the service would be gradual and orderly and based on necessity, as well as more efficient than that in 1941 and 1942. It is believed that the size of the pools would be small, with a consequent saving of countless physician man hours previously lost.

Professional training and supervision of young medical officers should be a constant objective of all senior medical officers. Young medical officers should have the opportunity to do supervised work. In addition some thought should be given to refresher courses for older medical officers. If this is impractical or inexpedient or if it imposes too large an administrative burden more consideration should be given to the utilization of professional skills in making duty assignments. Too frequently physicians with special skills such as roentgenologists were assigned as sole medical officers with isolated units. A refresher course in general medicine or a more appropriate duty assignment would resolve such a situation.

It is believed that civilian medical service during World War II was adequate and effective although it did impose a burden on the physicians remaining in civilian practice. An analysis of a questionnaire on medical care of civilians during World War II by Frank G. Dickinson, Ph.D., revealed that estimations of the increased patient load on civilian physicians during the war averaged 75 per cent. Most civilian physicians, especially in the smaller communities believed that no more physicians could have been spared for military service. Time spent doing examinations for Selective Service boards differed widely among the physicians in any community. It is believed that all qualified physicians in the community should have been required to serve on Selective Service boards.

In the event of another national emergency a reasonable division of the supply of medical services between military personnel and civilians must prevail. In the war about 40 per cent of the practicing physicians were taken into the armed forces leaving 60 per cent of the practicing physicians to take care of 90 per cent of the population that remained civilian. We believe that the next war will be as global in nature as the last was. In the next war however we may expect many casualties and great damage in our own country. During the last war most military physicians believed that there were too many doctors lo

military service and most civilian physicians believed that there were too few physicians left at home. These two beliefs are mutually compatible and indicate that the distribution of physicians, in the opinion of physicians themselves, was inequitable. This error must not be repeated in the next war. It is believed that the armed forces could get along with fewer physicians if they made greater use of laymen in administrative positions and employed more technicians for the performance of quasi-medical duties.

A board representing the medical profession and the surgeon generals' staffs empowered to set the policy for the utilization of all physicians could do much to correct the errors that were made in the past and to ensure a more adequate and integrated medical profession for the next great effort. Such a board might well consider the utilization of civilian and military hospitals with their staffs interchangeably for either type of case. The vast scope of atomic warfare might make this necessary.

Dr Macmillan then stated that the Committee on Officers' Reports had approved the report of the Committee on National Emergency Medical Service and recommended its acceptance.

Dr Feiner pointed out that physicians entered the service so fast that they were put into pools, which was not the only reason for misassignments. He believed that there were many cases in which no effort was made to place a man according to his experience and capacities in previous private practice, adding that he had seen breakdowns among men forty-five years of age who served in battalion aid stations and with tank-corps units. Conversely, in a general hospital, there were many young recent graduates with nine months of Army hospital training who were on general service, serving on the surgical service of a fixed institution and who knew nothing about surgery. The burden should have been carried by men with more experience.

The Speaker then asked for a vote on the motion to accept the report.

The motion was carried.

Dr D. G. Smith expressed approval of the report of the Committee on National Emergency Service, adding that the House of Delegates of the American Medical Association at its recent meeting had voted to approve the following recommendation: that the Congress and the President of the United States be respectfully urged to provide that the surgeons general of the Army, Navy and Air Force be made members of the Joint Chiefs of the General Staff, to require that the Secretary of the Navy and the Secretary of War, or other cabinet officers charged with the responsibility for national defense in the planning, location and construction of military hospitals in their wartime utilization, give consideration to possible civilian wartime requirements, and that they re-examine their organizational tables and other procedures used during World War II, to avoid a repetition of medical overstaffing of units, the wasting of the time of doctors of medicine in the performance of unprofessional duties, which could have been performed effectively by nonmedical personnel, removal of the excessive number of doctors of medicine from civilian hospitals and civilian prac-

tice and an effort to avoid the rather widespread failure to make assignments, determine rank and provide for the rotation of doctors of medicine on the basis of their professional qualifications, experience and age. It was also recommended that a National Emergency Medical Service Administration be created as a continuing function of government, considering the representatives of American physicians and surgeons, in such organizations as the American Dental Association, American Medical Association, American Nurses' Association, American Veterinarian Medical Association and Association of American Medical Colleges. The next recommendation was that the responsibility at all times for effective plans for total mobilization of the medical and allied resources of the nation was the duty of the national administration. The final recommendation was that the Committee on National Emergency Medical Service be continued until such time as the purposes for which it was created have been fulfilled. It was voted that the states be asked to continue their committees on national emergency medical service.

The next report was that of the Committee on Tuberculosis.

The year 1946 recorded a definite increase in the mortality from all forms of tuberculosis in New Hampshire as compared with the all-time low of 1945. The Division of Vital Statistics of the New Hampshire Department of Health reports a total of 115 deaths and a death rate of 24.8 per 100,000, as compared with 96 deaths and a rate of 21.9 in the preceding year.

The statistics for the other states and the nation as a whole are not available at present. Therefore, it is not possible to present a comparative study of the position of New Hampshire among the states as it relates to tuberculosis mortality in 1946.

In 1945, however, New Hampshire occupied an enviable position among the states in this respect. It had the lowest tuberculosis death rate in New England, 21.9 per 100,000 population as compared with a rate of 31 in Maine, 33.2 in Rhode Island, 35.4 in Vermont, 37.2 in Connecticut and 39.3 in Massachusetts. Among the states New Hampshire was in the seventh place among the states with low rates: Wyoming, 10.9; Utah, 12.8; Nebraska, 15.4; Iowa, 15.7; Idaho, 16.2; Kansas, 19.5; and New Hampshire, 21.9. New Hampshire's position is particularly noteworthy in view of the fact that it stands third among the states from the standpoint of population to industrial employment, Rhode Island standing first and Massachusetts second.

The increase in tuberculosis mortality for New Hampshire for 1946 is approximately 20 per cent—or 4 points in rate—as compared with the previous year. Several important criteria must be considered in evaluating the 1946 tuberculosis mortality. The trend in the death rate from an infectious disease is based on the evidence of increase or decline over a three-year or five-year period. On that basis, the tuberculosis death rate has persistently declined in New Hampshire over the past thirty years: from 1916 to 1920 the annual average rate was 114 per 100,000, from 1921 to 1925, 76.8, from 1926 to 1930, 59.7, from 1930 to 1935, 30.6, and from 1941 to 1945, 25.2. Furthermore, some fluctuation is to be expected in the tuberculosis death rate from year to year, especially in that for a state with a small population.

The apparent increase in New Hampshire in 1946 follows a sharp decrease of approximately the same magnitude in 1945. The reported rate for the three-year period 1939 to 1941 was 27, and that for the three-year period 1942 to 1944 24.5. The rate then dropped to 21.9 in 1945, and

in 1946 returned to approximately its earlier level. The corresponding number of deaths was an annual average of 135 for the years 1939 to 1941, 117 for 1941 to 1944, 96 for 1945 and 115 for 1946. In relation to the figures for other years the death rate for 1945 is seemingly aberrant, and little or no significance can be attached to the apparent increase in the rate for 1946.

Under the continued leadership of the medical profession and the organized public-health and voluntary agencies, the program for the eradication of human tuberculosis is marching on to increasing success. We are fully cognizant of the fact that more effort and aggressive campaigning are required to maintain and reduce still further a low tuberculosis death rate than a high one.

The committee wishes to re-emphasize that the most important of all case-finding agencies in the state of New Hampshire in the fight against tuberculosis continue to be the practicing physicians. It is almost always true that the family physician has the first opportunity not only to ascertain the presence of active pulmonary tuberculosis but also to give battle for the cure of the afflicted and the safeguarding of the other members of the family from the tubercle bacillus, for it is the family physician to whom most people go when troubled by signs of ill health.

The records in the chest diagnostic clinics prove that the physicians of the state, if they are determined to do so, can perform a better job of suspecting and discovering active tuberculosis cases, year in and year out, than any other agency. It is noteworthy that in the past year, as in other years, more cases of active pulmonary tuberculosis were found among the referrals by physicians to the chest diagnostic clinics than in any other groups of people examined.

The Committee wishes again to urge increasing use of chest x-ray examination. It is now clearly demonstrated that tuberculosis can be seen on the chest x-ray film before it can be heard by use of the stethoscope. This is particularly true in the discovery of early or minimal cases.

Over 4300 chest x-ray films were taken in the case-finding programs in the chest diagnostic clinics, schools and colleges in 1946, in addition to the large numbers taken in the hospitals throughout the state.

We urge continued use of the tuberculin test, particularly among young people, and efforts for the discovery of possible "spreaders" among the adult contacts of children presenting positive reactions to the test.

Efforts for the promotion of routine chest x-ray examination for all patients admitted to general hospitals have been handicapped because of lack of personnel and the rationing of x-ray films. It is hoped that an evaluation of this case-finding procedure can be made in one or two hospitals in the near future.

During the past year there has been a considerable amount of publicity in the newspapers and magazines about a newly discovered "cure" for tuberculosis—streptomycin. According to reports from the United States Public Health Service and the National Tuberculosis Association this publicity has given an unjustifiably optimistic picture. Despite considerable research activity it is stated by these sources that the full value of streptomycin treatment is not yet known and that the indiscriminate use of the drug is not advocated by medical opinion. According to present indications, streptomycin in the treatment of pulmonary tuberculosis appears to have its greatest usefulness if given in the early stages of the disease, in the later stages, when there has been extensive destruction of lung tissue, the drug has shown little to encourage a belief in its effectiveness. In some minimal cases, good results have been reported, but most patients with minimal cases recover on older methods of treatment without the use of streptomycin.

To advocate the indiscriminate use of streptomycin, especially in moderately advanced or advanced cases of pulmonary tuberculosis, not only is premature but also carries with it certain dangers and drawbacks. Among the principal dangers in the use of this drug is its toxicity, which may seriously affect hearing, sight and kidney function and cause skin eruptions. At present, it can only be said that we have seen little in the treatment of well-established pulmonary tuberculosis by streptomycin that gives cause for any great optimism regarding its curative value.

The use of streptomycin, however, has stimulated the development of research activities by national health agencies and other groups. There remains the possibility, not yet explored, that streptomycin or some related mold offers a chance for the discovery of a curative measure of value. It is believed that years of careful research will be required to bring forth the facts concerning the value of streptomycin.

During the past year considerable attention has been directed to the possible use of BCG (Bacillus-Calmette-Guérin) in this country as an immunizing agent against tuberculosis. In 1908 Calmette and Guérin announced in Paris the development of a particular strain of bovine tubercle bacillus that had lost its virulence twelve years later they reported that this culture was harmless to man and was effective in bringing about some measure of immunization against tuberculosis. Several million vaccinations have been performed since the initial work with human beings in 1921. Although extensive vaccinations have been carried out in Europe and South America, and careful studies undertaken in the United States BCG vaccinations have not been well accepted in this country.

Last September a conference on BCG vaccination was held in the offices of the Tuberculosis Control Division of the United States Public Health Service. The consultants constituted an assemblage of tuberculosis authorities in the United States and from Denmark and China.

Briefly, a few of the conclusions were that BCG should not be made commercially available at present, that a single laboratory be established by the Tuberculosis Control Division of the United States Public Health Service to produce BCG vaccine for the whole country for use in research programs proposed at the conference, that extensive investigations be carried on co-operatively with recognized research groups throughout the country during the coming years, especially in population groups highly exposed to tuberculous infection and that the United States Public Health Service set up a controlled study in a community containing 100,000 or more people, to determine immediate and long range results.

Although discoveries have been and are steadily being made it is well to remember the advice. Be not the first by whom the new is tried, nor yet the last to lay the old aside. Research and experiment will determine the value of the new drugs and treatments, but it is poor judgment to discard anything good unless for something really better. The value of BCG is still the subject of argument, and streptomycin is not a demonstrated aid in cure and has serious disadvantages. In New Hampshire experimental methods seem to be out of place while the well demonstrated fundamental procedures in the discovery, diagnosis, prevention and treatment of tuberculosis continue to win results. We must continue and extend these well developed resources, ever hopeful that a cure or preventive for human tuberculosis will be found and thus hasten the victorious conclusion of our struggles.

One of the members of our Committee Dr. Richard C. Batt, has left New Hampshire hence this paper is prepared by the other two members.

ROBERT B. KERR, Chairman
JOHN D. SPRING

Dr. Macmillan, for the Committee on Officers' Reports, recommended adoption of this report.

This motion was duly seconded and was carried.

Dr. Perreault, in presenting the report of the Committee on Communications and Memorials, read the following communication to Dr. Metcalf from Dr. Norman H. Gardner, of the Committee on Rural Medicine of the American Medical Association.

I am writing to again urge you to form a state Committee on Rural Medical Service to co-operate with the national committee. It is now more than ever essential that organized medicine present a common front of interest in the welfare of the rural dweller. I need not remind you that organized medicine has been attacked by many in the immediate past. The farmer has given all in-

dications of being anxious and willing to work with us to formulate plans for improvement in the medical situation of those living in rural areas.

There is much of a constructive nature that a Committee on Rural Medical Service can accomplish. In your state as in my own I presume that the problem is largely one of educating the farmer as to just what constitutes good medical care, and by what means he may attain the goal.

We in Connecticut are now in the process of planning our first Conference on Rural Health. The steering committee is most enthusiastic, and it looks as though we will have a very interesting conference.

Medicine has definitely taken the lead in this matter of rural health and we should continue to carry the ball now that we have it. There are not a few on the radical fringe who are most willing and anxious to step in and finish the job in their own way. We must not let this happen.

I sincerely hope that I will hear in the near future that your state has formed a committee on Rural Medical Service. I shall plan to meet with the chairman to talk over plans for the work of the committee in New Hampshire.

Dr. Perreault stated that the Committee recommended that a committee for rural medical service be appointed to co-operate with the national committee.

This motion was duly seconded.

Dr. Dye inquired whether the new group was to be a standing or a special committee.

Dr. Perreault replied that the Committee believed that it should be as standing as the national committee.

The Speaker then asked for a vote on the motion.

The motion was carried.

Dr. Perreault then read the following letter from Miss Helen E. Hinman, nutrition consultant of the State Department of Health, addressed to Dr. Sycamore.

Upon a request from Dr. Colin Stewart, I am writing you the reasons why I think a nutrition committee of the State Medical Society would help promote better nutrition in New Hampshire.

Through such a committee, advice and co-operation could be given on the publication of nutritional material by the State Health Department. Because of the recognition of the importance of nutrition in geriatrics, pediatrics, pregnancy and surgical cases as well as other diseases where nutrition is considered an important part of the treatment, it would be helpful if such a committee could give information on the latest nutritional research to the county organizations and suggest names of speakers to them in these fields.

It has been stated in the *American Medical Journal* that nutrition has been found to be important to a patient in the recovery of various surgical diseases. Therefore it is necessary for the physician to know the kind of foods the patient needs. It is no longer enough to give orders as "give the patient light, soft solid diet." He must now know the amounts of protein, vitamins and so forth the patient requires. And the now recognized routine in post-operative cases of intravenous alimentation with protein digest, plasma, and vitamins makes it a more complicated nutrition problem than it was formerly. Therefore, information of the latest research in this field becomes of aid to the physician.

In pediatrics the mass of information on nutrition obtained through the study of animals has been supplemented and augmented by the study of well and sick children. So that now nutrition in pediatrics includes much more than giving required amounts of appropriate foods in health. It requires an understanding of metabolic changes in diseases and the compensating for these changes.

In the whole field of nutrition nothing has been more dramatic than the studies done on nutritional requirements during pregnancy and the application of this knowledge is not only important for the patient but also for future generations. And yet, in many communities in New Hampshire, I find expectant mothers not getting necessary foods and physicians tell me that in some communities that they do not have more than two or three breast-fed babies in the town. Last month I visited a maternity home where the manager told me that they had not more than one breast-fed baby a year in that home. And yet, a recent report of Aldrich at Rochester gives seventy-five per cent breast feeding in their clinic. I think the physicians could do much to encourage breast feeding in their communities. We find pre-school feeding hardly ever a problem if infant feeding is right.

My work as nutrition consultant for the New Hampshire State Department of Health is to promote better nutrition for all age groups. I think a nutrition committee would be of great service to me in informing the physicians of the nutritional problems in their community and their advice and co-operation would help me in my work.

Dr Perreault then stated that the Committee did not consider the establishment of a new committee on nutrition to be quite essential, since there was already a committee on child health, maternity and infancy.

Dr Feiner expressed agreement, pointing out that the proposal presupposed that the majority of surgeons did not know about parenteral feedings, protein requirements and fluid balance and that the obstetricians did not know how to feed pregnant women, it threw the blame for bottle and formula feeding squarely on the shoulders of the doctors, when it is really the fault of the mothers, who insist on it. He did not believe that there would be much gained by instituting another committee involving additional expense.

A member moved that the recommendation of the committee be accepted.

This motion was duly seconded and was carried.

Dr Perreault then read the following communication from Dr Frederick J Vintinner, director of the Division of Industrial Hygiene, addressed to Dr John Samuel Wheeler, state health officer:

As part of the industrial health and hygiene program in New Hampshire it is believed that an active committee on Industrial Health, in the New Hampshire State Medical Society would aid materially in the advancement of this program among industrial officials and employees. While it is understood that the present Health Committee of the Society assumes these functions in addition to other problems relating to public health, a Committee on Industrial Health with members who are actively engaged in industrial medicine would be of considerable assistance in the development of standards, practices and procedures necessary for the development of good industrial health programs.

Committee membership of such physicians as Dr Robert Graves, Concord, Dr David Parker, Manchester, Dr Henry Almond, Berlin, Dr Robert W Holmes, Keene, and Dr Timothy F Rock, Nashua, would give representation of physicians actually engaged in industrial medicine.

Such a committee would be of great value to the Division of Industrial Hygiene, State Health Department, in the development and advancement of the industrial hygiene program in New Hampshire.

Dr Perreault stated that the Committee believed that a committee on industrial health should be appointed, unless there are other committees at the present time that could do this. He made a motion to that effect.

This motion was duly seconded and was carried.

Dr Perreault then asked for discussion concerning Senate Bill No 86, dealing with the sale of barbiturates. The bill was as follows:

Be it Enacted by the Senate and House of Representatives in General Court convened

1 DEFINITIONS For the purpose of this act,

I The term "barbiturate" means the salts and derivatives of barbituric acid, also known as Malonyl Urea having an hypnotic or somnifacient action, or compounds of any preparations or mixtures thereof.

II The term "delivery" means sale, dispensing, giving away, or supplying in any other manner.

III The term "patient" means, as the case may be, (1) the individual for whom a barbiturate is prepared or administered, (2) the owner or agent of the owner of the animal to which a barbiturate is administered or for which a barbiturate is prescribed.

IV The term "person" includes individual, corporation, partnership and association.

V The term "practitioner" means a person licensed by law to prescribe and administer barbiturates.

VI The term "pharmacist" means a person duly registered with the state commission of pharmacy as a compounder, dispenser, and supplier of drugs upon prescription.

VII The term "prescription" means a written order by a practitioner to a pharmacist for a barbiturate for a particular patient, which (1) specifies the date of issue, the name and address of the practitioner, (2) the name and address of the patient (and if such barbiturate is prescribed for an animal, the species of the animal), (3) the name and quantity of the barbiturate prescribed, (4) the directions for use of such drug, and (5) the signature of such practitioner.

VIII The term "manufacturer" means persons other than pharmacists who manufacture barbiturates, and including persons who prepare such drugs in dosage forms by mixing, compounding, encapsulating, entableting or other process.

IX The term "wholesaler" means persons engaged in the business of distributing barbiturates to persons included in any of the classes named in section 3, paragraph c.

X The term "warehousemen" means persons who store barbiturates for others and who have no control over the disposition of such barbiturates except for the purpose of such storage.

2 PROHIBITED ACTS No person shall I Deliver any barbiturate, except as provided in paragraph III of section 3 unless Such barbiturate is delivered by a pharmacist, upon an original prescription, and therefore is affixed to the immediate container in which such drug is delivered a label bearing the name and address of the owner of the establishment from which such drug was delivered, the date on which the prescription for such drug was filled, the number of such prescription as filed in the prescription files of the pharmacist who filled such prescription, the name of the practitioner who prescribed such drugs, the name and address of the patient, and if such drug was prescribed for an animal, the statement showing the species of the animal, and the directions for the use of the drug as contained in the prescription, or II Refill any prescription for a barbiturate unless as designated on the prescription by the practitioner, or III Deliver any prescription for a barbiturate unless the pharmacist who filled such prescription files and retains it as hereinafter required, or IV

Possess a barbiturate unless such person obtained such prescription by a practitioner or V. Refuse to make available and to accord full opportunity to check any record or file, as required herein VI. Fail to keep records as required herein or VII. Use to his own advantage, or reveal (other than to an officer or employee of the state department of pharmacy or to a court who is relevant in a judicial proceeding) any information required under the authority of section 4 concerning methods or processes which as a trade secret are entitled to protection.

3. **EXEMPTIONS.** I. Nothing in this act shall apply unless otherwise indicated by the practitioner to the refilling, at any time of a prescription for compounds, mixtures or preparations containing in addition to a barbiturate, sufficient quantity of another drug or drugs to cause the compound, mixtures or preparations to possess other than a hypnotic or somnifacient action.

II. Nothing in this act shall apply to any compound or mixture or preparation that is intended to be used as a spray or gargle or a liniment or in any other way for the external application if such compound, mixture or preparation contains in addition to the barbiturate, some other drug or drugs rendering it unfit for internal use and such compounds or mixtures or preparations shall be sold in good faith for the purpose for which they are intended and not for the purpose of evading this act.

III. The provisions of section 2, paragraph IV shall not be applicable (a) to the delivery of barbiturates to persons included in any of the classes hereinafter named or to the agents or employees of such persons for the use in the usual course of their business or practice or in the performance of their official duties as the case may be or (b) to the possession of barbiturates by such persons or their agents or employees for such use.

(1) pharmacists (2) practitioners (3) persons who procure barbiturates (a) for disposition by or under the supervision of pharmacists and practitioners employed by them or (b) for the purpose of lawful research, teaching, or testing and not for resale. (4) hospitals and other institutions which procure barbiturates for lawful administration by practitioners. (5) officers or employees of federal, state or local governments or (6) manufacturers, wholesalers, carriers, warehousemen.

4. **RECORDS.** I. Persons, other than carriers and practitioners shall keep complete records showing (1) all stocks of barbiturates on hand and (2) all receipts and deliveries of barbiturates by such persons their agents or employees.

II. Practitioners shall keep complete records showing (1) all stocks of barbiturates on hand July 1st, 1947, (2) all receipts of barbiturate by them, their agents and employees and (3) the name and quantity of each barbiturate dispensed or administered by them. (4) the date it was dispensed or administered by them. (5) the name and address of the patient, and (6) if such barbiturate was prescribed for or administered to an animal the species of the animal.

III. Pharmacists shall keep complete records showing (1) all stocks of barbiturates on hand July 1st, 1947 (2) all receipts of barbiturates by them (3) file each prescription received by them with appropriate number and date of each refill pursuant thereto, (4) retain such prescriptions for a period not less than two calendar years immediately following the date of the last filling or refilling (5) in the case of sales under the provisions of section 3 paragraph III, the names and quantity sold the date it was sold and the name and address of the purchaser.

IV. The usual commercial or other records maintained by manufacturers, wholesalers, practitioners or pharmacists with the exception of the inventory of the initial stock on hand shall suffice to meet the requirements of this section. Such records shall be preserved.

V. Persons required by this section to keep files or records relating to barbiturates shall upon the written request of an officer or employee duly designated by the state department of pharmacy (1) make such files or records available to such officers or employees at all

times for inspection and copying and (2) accord to such officers or employees full opportunity to check the correctness of such files or records including opportunity to make inventory of all stock of barbiturates on hand and it shall be unlawful for any such person to fail to make such files or records available or to accord such opportunity to check their correctness.

5. **REGULATIONS.** The state department of pharmacy is hereby authorized to promulgate necessary regulations for the administration and enforcement of this act.

6. **PENALTIES.** Any person who violates any of the provisions of this act shall be fined not more than one thousand dollars nor less than five hundred dollars.

7. **TAKES EFFECT.** This act shall take effect July 1 1947.

The following letter from the legislative committee of the New Hampshire Pharmaceutical Association was then read

June 3 1947

Dear Doctor

Medical practitioners and pharmacists have been subjected to unfortunate criticism by the general public by spokesmen for women's clubs, by the writers for pulp magazines and by the press in connection with the increasing amount of Barbiturates distributed per capita. This pressure has caused Congresswoman Edith Nourse Rogers (Mass.) to introduce the present Barbiturate Bill now before Congress. This Bill will provide for the safe keeping of records, inventories and inspections as for Narcotics.

To correct public opinion that Barbiturates are distributed indiscriminately by medical practitioners and pharmacists, and to avoid the onerous Federal regulations of pending legislation this state society has introduced on the state level the enclosed bill. Restrictions on both practitioners and pharmacists are at the minimum. Records are reduced to invoices of goods received and the usual medical notes made on the patient's case record in the doctor's office. (Duplicate printed original inventory forms will be mailed you from this office subsequent annual inventories are not required.)

There are no restrictions on the amount or frequency of administration or dispensing by the practitioner. No pharmacist may refill without specific directions.

The above facts should serve to correct completely the erroneous reports concerning the Bill circulated before it was ever printed.

A reading of the Bill will demonstrate that its object is protection for the public, prevention of undesired criticism of practitioners and pharmacists, and the reduction of restrictions to a minimum of state control rather than by Federal legislation.

The American Medical Association supports even the more restrictive Federal form of this same legislation. Dr. Austin Smith, Chairman of the Committee on Pharmacy and Chemistry, helped draft the legislation.

We look forward to your professional support of "Senate Bill No. 86."

Respectfully

HENRY J. ROBERTS
Chairman, Legislative Committee

Dr. Sullivan believed that the bill had originated with the Pharmaceutical Association, who apparently thought that regulation was needed. Incidentally, in regulating themselves, the Association proposed to regulate the medical profession. He stated that if the Pharmaceutical Association considered regulation regarding the dispensing of barbiturates to be necessary, the New Hampshire Medical Society should not be taken into the provisions of the bill, which would entail a great deal of work. Certainly, the Federal Narcotic Bureau did not demand such

strict accounting of narcotics as this bill demanded of barbiturates. He believed that these restrictions should be struck out entirely, and the provisions of the bill confined to regulating pharmacists.

Secretary Metcalf stated that at a recent hearing Drs Tuttle and Howard Sawyer had spoken, as well as the President of the Veterinary Association and Dr Metcalf.

About eight weeks previously, Henry Roberts, chairman of the Legislative Committee of the New Hampshire Pharmaceutical Association, had asked the New Hampshire Medical Society to support the bill. Dr Metcalf had heard nothing further from any member of the Pharmaceutical Association until after the bill had been submitted to the Senate. On the other hand, the Pharmaceutical Association sent out to each pharmacist a letter in which it was stated that the Secretary of the New Hampshire Medical Society had stated that he saw no objection to the tentative bill. Dr Metcalf pointed out to the Senate Committee that that was technically true — that he had not stated objection to the bill, nor had he stated that he favored it.

In the few remaining days Dr Metcalf communicated with about ten physicians in the state: two in Nashua, two in Manchester, two in Dover, two in Wolfeboro and two in Hanover and several in Concord, all of whom objected to the bill as it is now written because the barbiturates are now controlled by regulations of the New Hampshire Board of Health and this was apparently an effort on the part of the Pharmaceutical Association to take the authority away from the Board of Health and transfer it to the Department of Pharmacy — a sort of jurisdictional quarrel.

One objection was the paper work involved in keeping this list of barbiturates and the name of the patient and the reason for which it was given, the amount that was given and so forth. When that objection was raised, Dr Metcalf was told that it would not be necessary to keep a special list but that the regular office records of the patient would suffice, to which he replied that the regular office records contained other data, such as the history of the patient, the diagnosis and the clinical findings, and that those should not be open to inspection, because the Pharmaceutical Association proposed under this bill to send an inspector to the doctor's office to examine the records.

The next objection was that the penalties were too high. The minimum fine was \$500, and the maximum \$1000, which perhaps would not be too high for a physician, if there is one in the state who is giving these drugs to addicts, but it was certainly too high for any honest doctor who simply had a record that was not complete.

Then, Dr Metcalf had told the Senate and Mr Roberts had also told the Senate that this particular bill, as written, should be tabled, that if there was any need for legislation, the pharmacists should get

together with the doctors and the Board of Health and work out any legislation that was needed, the pharmacists, as a matter of fact, had written the bill without consulting either the Board of Health or any doctors.

Dr D G Smith then observed that the statement that the American Medical Association had supported even the more restrictive federal forms of this same legislation was absolutely untrue, of which he had proof in the minutes of the meetings.

Apparently, in some states, there was necessity for the regulations. In 1945 fourteen states and the District of Columbia had no restrictions on these barbiturates, so that they could be sold over the counter. One of the states was Massachusetts. In some states, where the laws had been passed prohibiting the sale of the barbiturates over-the-counter, it was not enforced. There had been an effort to draft a uniform barbiturate bill, and it stated in the hearing that such a bill has been presented in some of the states. One of the senators from New Hampshire said that the testimony at the hearing was that this bill was introduced in the New Hampshire Senate as the uniform bill.

Mr Holloway, director of the Bureau of Legal Medicine, stated that the New Hampshire bill was not the uniform bill, that the bill as introduced in the various states had some defects and that in July or early August, he was going to meet with the counsel of the American Pharmaceutical Association and another group to draft uniform state regulations in an attempt to draw up a uniform barbiturate bill that would be acceptable. When he was told that physicians in New Hampshire were trying to kill the present bill, he replied that he thought they were justified in doing so.

Of three senators on the Public Health Committee of the Senate, one had definitely stated that he would go along with the doctors, one was favorable toward physicians, and the third appeared to be on the fence. Dr Smith had been informed, however, that the bill would not be reported out of committee, which would shortly meet again.

Dr Dube moved that the House of Delegates go on record as opposing Senate Bill 86.

This motion was duly seconded and was carried.

Dr Dye asked if someone were going to be delegated to inform the Senate Committee about the Society's stand.

The Speaker replied that the President of the Society would take such steps.

Dr Perreault then referred to a communication from Dr Oppenheimer, asking if the Society could organize or become connected with a good medical library from which members could borrow books and periodicals without red tape, high cost and waste of time. It was the opinion of the Committee on Communications that that would not be necessary, for most large cities had their own libraries and medical libraries were available.

Dr Brody inquired what was meant by the statement that medical libraries were available.

Dr Perreault replied that at Harvard Medical School one could find all the material desired and that, through the American Medical Association, necessary information could be obtained. The American College of Surgeons also had a library, where one could look up information. At Rochester, a recent but fairly active library was available to all the members of the New Hampshire Medical Society.

The Speaker pointed out that no action was required on this matter.

The Delegate to the American Medical Association, Dr Deering G. Smith, then presented the following report:

Three sessions of the House of Delegates of the American Medical Association have been held since the last meeting of the Society, and to make this report brief only the high spots will be brought to your attention. Your delegate served on the following important reference committees at each session—Legislation and Public Relations Executive Session and Reports of Officers.

At the San Francisco session President Roger Lee urged a wider participation of physicians in public and world affairs. Since the younger members of the medical profession will be most concerned with the changing order of medical practice, they should have a large share in the affairs of county and state societies and in the American Medical Association. Dr Olin West resigned after being secretary for twenty-four years. Dr West was chosen president-elect, but this spring he had to resign because of ill health. He was succeeded by the vice-president, Dr Edward L. Bortz, who is now president. Dr George F. Lull retired from the Army after serving as deputy surgeon general, was selected as secretary and is filling the position in an admirable manner.

In view of the agitation for a second medical school in this state, it seems advisable to summarize the requirements for a new medical school as was brought out in a committee report: Initial expenditure of millions and annual budget of \$350,000 for the school alone, full time clinical instructors, ample supply of ward patients and competent instructors, including specialists. The annual number of graduates from the existing schools is adequate for the peacetime needs of the country; granted distribution is equitable. In New Hampshire the physician population has increased more than the general population and even the rural areas have adequate medical care.

A resolution was unanimously adopted that "proposed legislation such as that of S. 1606 (relating to compulsory health insurance), if ever enacted, would seriously jeopardize the proper and adequate care of sick people in the United States."

To improve the public relations of the Association it was voted to stress the scientific activities through the *Journal* and through an expanded *Hygiene* to expand the Bureau of Medical Economics with the employment of competent economists and to appoint an executive assistant to the general manager to co-ordinate all public relations activities other than scientific. At the supplemental session held at Chicago in December this was amplified to include the description and dramatization of the progress of scientific medicine and the history of organized medicine in the United States, as well as increased activity in health education by means of the radio and motion pictures.

At this supplemental session there was some discussion of the general practitioner and the Section on General Practice was requested to give consideration to a plan for the establishment of a certifying board. The following resolution was voted:

Hospitals should be encouraged to establish general practice services. Appointment to a general practice section shall be made by the hospital authorities on the

merits and training of the physician. Such a general practice section shall not per se prevent approval of a hospital for the training of interns and for residencies. The criterion of whether a physician may be a member of a hospital staff should not be dependent on certification by the various specialty boards or membership in special societies.

This statement was repeated and amplified at the recent session at Atlantic City. It was most fitting that the discussions in the House of Delegates at this centennial session should center on the general practitioner or family doctor. This was also true at the Conference of County Medical Society Officers held this year for the first time. It was agreed that a place must be found in the hospitals for the general practitioner who does the major portion of the medical work, and that there must be no discrimination against him and no priority given to specialists in admitting patients to the hospitals. Every patient should have the free choice of his physician, even in a hospital. There is an insufficient number of hospital beds, owing partly to the demands of members of hospitalization plans and county societies should stimulate additions to hospitals. It was suggested that medical films, of which the American Medical Association has many, as well as lists of all others, be used to increase attendance at county meetings and that the rural general practitioners be urged to read papers. In some societies lectures are given to all new members, stressing the history and structure of organized medicine, public relations and the prevention of malpractice suits. In other societies there is a probationary period of six to twelve months, during which the applicant has all privileges except voting before he becomes a full member. It was voted to have another conference next year, and it was suggested that each state organize a county secretary society. This state had meetings of the county secretaries years ago that were well attended and of great value.

The Atlantic City session—the one hundredth anniversary—was attended by over 15,000 physicians, the largest attendance by many thousands, in the history of the American Medical Association. Foreign guests, leaders in their countries, were present and read papers. Distinguished nonmedical persons gave addresses. A stamp commemorating "The Doctor" was issued, and President Truman sent a cordial message. President Shouder stated "that the immediate and most urgent needs are concerned with increasing the availability of the services of General Practitioners." There is too much specialism and the reorganization of general practice is necessary. Following his recommendations it was voted to request the Board of Trustees to appoint a special committee including a number of general practitioners to study and report on all the factors that affect the production and distribution of the type and quality of medical care that the people need or desire.

A year ago the supplemental session of the House of Delegates was instituted and this year it was decided that this annual session would be held in various sections of the country to be preceded or followed by a scientific session devoted exclusively to the general practitioner.

It was recommended that, to obtain a greater number of well qualified speakers, the Council on Medical Service assist in the establishing of a speakers' training program and speakers' bureau in every county medical society, bring its pamphlets up to date and prepare a number of basic speeches for distribution through the speakers' bureaus.

Many county and state societies have overlooked the potent public relations value of their women's auxiliaries and it was voted to urge the societies to have their auxiliaries make use of available material at the headquarters office.

The nursing crisis was discussed and the president was asked to appoint a committee to investigate the present objectives of the nursing profession, the standards of education, the time involved for training, the various curricula, the supply of nurses and quality of services rendered, remuneration, participation in the determination of administrative policies, the question of security benefits and the study of the training of practical nurses.

Thirty-eight states have worked out plans for home-town medical care of the veteran and the Veterans Administration

approve Dr Ford's acceptance of an appointment to this committee.

The Secretary pointed out this was a committee of ophthalmologists, who met at specified intervals with the Department of Public Welfare, to consider the care of the blind, and to advise on proper measures to be taken by the Department of Public Welfare. This was a formality to add Dr Ford to this Consulting Committee.

Dr Macmillan moved that Dr Ford be added to the Medical Advisory Committee of Ophthalmologists.

This motion was duly seconded and was carried.

The Speaker stated that at the meeting on the previous evening, every delegate was present except one, who sent a letter of explanation to say that he could not come and for whom there had been an alternate. At the morning session, all were present except two.

Dr Parsons then proposed the following names for life membership: Drs E R Dell, of Berlin, R E Webb, of Lancaster, and John M Blodgett, of West Stewartstown. Dr Feiner moved that the names be accepted.

This motion was duly seconded and was carried.

Dr Dye then presented the proposed amendment to the by-laws, as brought forth the previous night and laid on the table for one day. It was more or less a matter of routine to change Chapter VIII, Section 1, of the by-laws, under the heading of Committees, and add, "A Committee on Industrial Health" and also to add "A Committee on Rural Medical Service." These additional committees would occupy an additional section at the end of Chapter VIII. He moved that these changes in the by-laws be accepted.

This motion was duly seconded and was carried.

Dr Macmillan stated that the Committee on Officers' Reports wasted a great deal of time in reading in detail some of the long reports, and he wondered if the committee could bring in a summary of those reports and bring out the salient features, that would give an opportunity for more time for discussions.

Dr Dunbar recalled having experienced the same difficulty when he had been chairman of the committee. He believed that if some changes could be made, it would save a good deal of time.

The Speaker asked if it would be feasible to mimeograph reports and send them to the delegates.

The Secretary replied that such a procedure had been tried one year, the reports had been late in coming in, the synopses had been fragmentary, and the change had seemed not to be worth while. He stated that if the Chairman of the Committee on Officers' Reports could make brief abstracts of the various reports, he would be glad to have them printed or mimeographed and sent to each delegate in advance, it would give the delegates some idea of what was coming up.

The Speaker asked if it would be possible to mimeograph the full reports, if they came in on time, and then have the Chairman of the Committee on Officers' Reports present the synopsis at the meeting for discussion.

The Secretary answered that that would be possible. It would involve a good deal of work and expense, but he would be glad to do anything the House of Delegates directed, to get the information out.

Dr Macmillan moved that it be the duty of the Committee on Officers' Reports to submit at the time of the meeting of the House of Delegates a summary of each committee's report, to be read in place of the full report, except in cases in which the report was requested to be read in detail.

Dr Lewin stated that during the previous year he had received two of the reports after he arrived at the medical meeting, which was held about two hours before the delegates' meeting.

Dr Dunbar stated that it appeared to him that the Secretary knew the technical difficulties of the situation and that the matter should be left to the Secretary's discretion.

The Speaker called for a vote on the motion.

On a showing of hands, 12 were for the motion, and 6 dissented, therefore, the motion was carried.

The second meeting of the House of Delegates was adjourned at 9:45 a m.

* * *

The House of Delegates reconvened at the Wentworth Hotel, Newcastle, on June 20, 1947, at 9:00 a m with Speaker Sycamore, of Hanover, presiding.

The following members answered the roll call:

The President, *ex-officio*
 The Vice-President, *ex-officio*
 The Secretary-Treasurer, *ex-officio*
 Samuel Feiner, Ashland
 Nathan Brody, Laconia
 W J Paul Dye, Wolfeboro
 Francis J C Dube, Center Ossipee
 Marjorie A Parsons, Colebrook
 Joseph E Larochelle (alternate for Francis M Appleton)
 Israel A Dinerman, Canaan
 Leslie K Sycamore, Hanover
 Clarence E Dunbar, Manchester
 Daniel J Sullivan, Nashua
 Samuel Fraser, New Boston
 Loren F Richards, Nashua
 Robert R Rix, Manchester
 Philip M L Forsberg, Concord
 Andrew L MacMillan, Concord
 Francis Brown, Henniker
 John W Blaisdell, Epping
 Donald W Leonard, Exeter
 Fred Fernald, Nottingham
 Raymond R Perreault, Rochester
 B Read Lewin, Claremont

The necrologist then presented the following report:

Report of the Necrologist

The following members of the New Hampshire Medical Society have died since the last report of the necrologist:

NAME	DATE OF DEATH	PLACE
Black, James S	April 21 1947	Nashua
Claggett, Fred P	July 4, 1946	Newport
Fox, George L.	November 3, 1946	Exeter
Greeley, Philip H	December 2 1946	Concord
Kendall, Anton H	November 9, 1946	Walpole
Michon, Nicholas D	March 21 1947	Manchester
Sanders, Loren A.	April 29, 1946	Concord
Sprague, Fred A.	December 3 1946	Concord
Thibodeau, Edgar J	January 15 1947	Berlin
Wiggin, Henry M	June 29 1946	Whitefield

Dr MacMillan, for the Committee on Officers' Reports, moved that the report of the necrologist be accepted

This motion was duly seconded and was carried

Dr Dye then presented the names of the candidates for president, for which office three names were submitted and voted on by written ballot John A Hunter, of Dover, the present vice-president, Samuel Fraser, of New Boston, and Edward R B McGee, of Berlin

The President moved that nominations be closed

This motion was duly seconded and was carried

The Speaker appointed Drs Dube and Dinerman to act as tellers

The voting then took place, and the tellers reported that Dr Hunter had received 19 votes out of 20

The Speaker then declared Dr John A Hunter duly elected as president for the ensuing year

Dr Dye presented the following nominations for vice-president Clarence E Dunbar, of Manchester, Harry T French, of Hanover, and Robert W Holmes, of Keene.

The voting then took place, and the tellers reported that Dr Dunbar had received 15 and Dr French 5 votes

The Speaker declared Dr Dunbar duly elected as vice-president for the ensuing year

Dr Dye then read the rest of the slate of officers and committees to serve for the ensuing year

The Secretary called attention to an error made by the Chairman of the Committee on Constitution and By-Laws, who had re-elected the Secretary The Secretary had been elected last year under Article 8 of the Constitution, which says that the Secretary-Treasurer shall be elected for a term of five years

Dr Macmillan moved that the nominations be closed

The President moved that the Secretary cast one ballot for the nominations as read

This motion was duly seconded and was carried

The Speaker then declared the officers whose names had been read as elected for the ensuing year

Dr Lewin, on behalf of the House of Delegates, expressed the appreciation of the House to Lester R Whitaker, president of the Rockingham County Medical Society, and to the President of the Rockingham County Women's Auxiliary, for the fine hospitality they had shown at the first meeting in

Rockingham County since 1927 He moved that this note be added to the minutes of this meeting

This motion was duly seconded and was carried

Dr Parsons presented the name of Dr Louis Marcoux for life membership

This motion was duly seconded and was carried

Dr Leonard stated that, at a meeting of the Rockingham County Medical Society, considerable discussion about the fees for relief cases had taken place He wondered if an expression of opinion might be enlightening to the Committee on Medical Economics in some way so that they might consider the matter

Dr Perreault replied that, at the last meeting of the Strafford County Medical Society, the same opinion had been unanimously expressed and that the delegate had been instructed to present this matter to the House of Delegates The belief was that there was no reason why the doctors should take a cut in their fees, when the druggists, the dealers in coal, fuel and so forth had not taken a cut.

Dr Lewin referred to a similar discussion in Sullivan County and to a talk with the county commissioners regarding county work He hoped that the commissioners had received a picture of the situation, they were considering the old Blue Cross fees for relief cases

Dr Parsons observed that Coos County had also brought this up at its meeting and that, last year, they had presented the same proposal but, instead of having the fees raised, had been given a schedule that was even less

Dr Dinerman referred to a resolution that was passed at the meeting of the House of Delegates in Manchester, with a schedule of Blue Cross and Blue Shield fees to be called to the attention of the Commissioners of Public Welfare, with the recommendations that these fees be the accepted fees He saw no objection to passing a resolution, but he wondered whether physicians were any nearer to getting what they wanted

The President mentioned the necessity of direct contact with the Commissioners of Welfare A resolution would have little effect.

Dr Leonard asked if the Committee on Medical Economics had not already been appointed to take care of such matters

The Speaker replied that the specific duties of the various committees were not very accurately defined He did not know whether the responsibility would come under that committee or under a special committee of the officers, that would be according to the pleasure of this House of Delegates

The Secretary pointed out that the Society had made a similar effort twice previously, with meetings and conferences with the Board of Public Welfare and all the county commissioners Nothing constructive had been accomplished The chairman of the Welfare Committee had said that he thought that physicians should be willing to take a cut in price because they were getting so much

experience out of these cases. The only solution seemed to be by some form of extra taxation. The motion passed during the previous year had been sent to the Board of Welfare, the motion being that the Society would like to put into effect for these cases the allowances on the Blue Shield schedule, the recommendation was pigeonholed.

Dr. Parsons stated that the points objected to on the fee schedule particularly in Coos County were the \$1.00 fee for complete obstetric care and the facts that mileage was no longer allowed and that only three calls per week at \$1.00 per call were permitted. Dr. Appleton had spoken in Gorham of the fact that he had happened to have one patient in the Berlin Hospital and that he had traveled a round trip of thirty-two miles to the hospital, with no mileage and no depreciation on his car.

Dr. Feiner asked if Senate Bill 86 would take care of the situation.

The Speaker replied that the proposed legislation might help the situation.

Dr. Dye moved that the Committee on Medical Economics include this as one of their functions to let them know all about the Blue Shield, and communicate with the Commissioners of Public Welfare, to see if the same sort of schedule as the Blue Shield could be obtained for the welfare cases.

This motion was duly seconded and was carried.

The Secretary stated that the Society had met in Manchester for a good many years, and that seemed to be impossible at present, except for a one-day meeting, because no rooms for overnight were available. The only solution for the present, at least, seemed to be to pick a summer hotel of this type and have the meeting in June or September, rather than in May. The center of the medical population, of course, was in the southern part of the state, and there were two hotels that were in the convention business on the scale that was needed. One of these was the Wentworth Hotel, and the other was at Bretton Woods. The question arose, therefore, whether one or the other of those hotels should be taken, and which one.

The disadvantage of Bretton Woods was the distance. There was no local committee in Bretton Woods to take care of the details of the meeting, so that it would mean that the group of delegates would have to go up once or twice before the meeting and make the arrangements and break the hotel staff in.

One difficulty about the Wentworth Hotel pertained to the exhibits. Some of them were very heavy, and the owner of the hotel, Mr. Smith, had been disturbed this year for fear that the doctors were going to break up his furniture and ruin his floors by moving in all the two-ton material. He rather questioned whether he wanted the meeting another year, if it would cost him a good deal of painting, revamping and so forth. He would probably be glad to have the doctors another year, if the ex-

hibits were not held or were held on a somewhat more limited scale, cutting out the heavy exhibits, which are apt to break his furniture.

Four or five conventions were signed up for June, 1948. The Secretary had taken the liberty of asking Mr. Smith to reserve tentatively the dates of June 16, 17 and 18, in the event that the Society wished to return next June, it would be a good idea to make reservations in advance rather than to wait until the fall, when the whole month of June would probably be taken up.

Dr. Hunter stated that the exhibitors believed that the delegates had not visited them too frequently anyway and wondered if, in the event that the meeting were held in the same place, it would be possible to eliminate the heavy-weight class and perhaps have the exhibits in the foyer. In that way, there would be fewer exhibits, and certainly the men would see them, or at least go by and give the impression that they were more interested than they had been this year.

Dr. Kennard stated that the exhibitors wished the delegates to visit them. So far as the Society was concerned, one of the chief reasons, of course, for having them here was the economic advantage the exhibitors paid quite well for the expenses of the convention. All bills were not yet in, but the exhibitors would probably net around \$1500, which was something to be considered.

The Speaker called attention to two papers presented on the previous day, starting at 11:15 a.m., which carried the meeting up to lunch time, at 12:30 p.m. The Program Committee could put on one paper at 11:15, which would carry the meeting up to 12:00, and it could be definitely stated on the program that the period from 12:00 to 12:30 was the time for visiting the exhibits.

Dr. Dye moved that the House of Delegates meet at the Hotel Wentworth on June 17 and 18, 1948, and that the question regarding the exhibitors be left to the discretion of the Committee on Scientific Work, the President and the Secretary and their designated agents.

This motion was duly seconded by Dr. Dube and was carried.

The Secretary pointed out that the Hotel Wentworth could not furnish the accommodations for the round-table conferences, only bedrooms being available this year, and the maximum number of people in a bedroom was about twenty. Some of the rooms had been overcrowded on the previous day, with a few people sitting on the floors.

The Speaker suggested leaving that matter to the Program Committee for consideration.

Dr. Dube moved that the meeting adjourn.

This motion was duly seconded and was carried.

Whereupon the final meeting of the House of Delegates was adjourned at 10:00 in the morning.

CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITAL

Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C CABOT

TRACY B MALLORY, M.D., *Editor*BENJAMIN CASTLEMAN, M.D., *Associate Editor*EDITH E PARRIS, *Assistant Editor*

CASE 33431

PRESENTATION OF CASE

A forty-four-year-old unmarried woman entered the hospital because of abdominal swelling.

The patient had felt perfectly well until one year prior to admission, when she began to look "worn out," and a few months later she began to experience gradually increasing fatigue and anorexia. Four months before admission, she noted swelling of the ankles, and a physician told her that she had sugar in the urine and a "swollen abdomen." One and a half weeks before entry she developed a sore throat, a temperature of 102°F and malaise and had subsequently remained bedridden. Three days prior to admission an abdominal paracentesis was performed, with the removal of 6 liters of fluid. A mild icteric tract of the scleras was noticed at that time. During the previous "year or two," the patient had lost 25 pounds. In the preceding fifteen years, the patient had consumed an average of 3 pints of distilled liquor a week, which she had increased to a pint a day for the past year.

Her father had died of tuberculosis at the age of forty-one years, and a sister of "tuberculous dysentery" at the age of sixteen years.

Physical examination revealed many spider angiomas over the abdomen, chest and arms. There was slight icterus of the skin and scleras. The tonsils were enlarged and boggy, and the pharynx was reddened. The cardiac impulse was felt 1 cm to the left of the midclavicular line in the fifth interspace, and a Grade III apical systolic murmur was present. The mitral first sound was accentuated. The abdomen was distended, firm and tympanitic, with dullness in the flanks. A fluid wave was present, and a firm, irregular, tender liver edge was palpated four fingerbreadths beneath the costal margin. The spleen was felt two fingerbreadths beneath the left costal margin. There was slight edema of the ankles.

Examination of the blood showed 12.6 gm of hemoglobin and a white-cell count of 15,000, with 92 per cent neutrophils. Urinalysis revealed a specific gravity of 1.010 and ++ test for albumin, and the sediment contained a moderate number of

white cells and occasional red cells. Repeated stools were guaiac negative. A cephalin-flocculation test was ++++ in twenty-four hours. The prothrombin time was 23 seconds (normal, 19 seconds). A van den Bergh reaction was 4.6 mg per 100 cc direct, and 5.8 mg indirect. The nonprotein nitrogen was not elevated. The blood cholesterol was 156 mg per 100 cc, with 54 mg of esters.

An x-ray film of the chest showed homogeneous linear areas of density in both lower-lung fields, more marked on the right. There was a small area of fibrosis in the first interspace on the left. The diaphragm moved well, and the heart was within normal limits in size and shape. A barium swallow disclosed an esophagus of normal caliber, no varices were seen. A plain film of the abdomen showed the tip of the liver to lie at the level of the iliac crest. The tip of the spleen did not appear unusually low. The kidneys were poorly outlined. There was a suggestion of a soft-tissue mass in the pelvis, which may have represented the gall bladder. On a repeated chest x-ray film ten days after admission the lung fields were clear except for several areas of linear density in the left lower-lung field and a linear area in the right lower-lung field. The blood sodium was 115.4 milliequiv, the chloride 88 milliequiv and the carbon dioxide 17.4 milliequiv per liter. A prothrombin time done eighteen days following admission was 30 seconds.

The temperature, which had been 101.5°F on admission, fell on the first hospital day, and after remaining only slightly elevated for a week, rose gradually. The pulse varied from 90 to 135 during the hospital stay. On the fourth day, an abdominal paracentesis produced 4000 cc of fluid, with a specific gravity of 1.003 and containing 895 red cells and 160 white cells per cubic millimeter, of which 125 were lymphocytes, 25 polymorphonuclears and 10 monocytes. The patient had a slow, steady, downhill course, the dyspnea becoming marked, and the patient semicomatose. Petechial hemorrhages appeared on the conjunctivas, scleras and skin of the arms, and there was some bleeding from the mouth. She died after three weeks of hospitalization.

DIFFERENTIAL DIAGNOSIS

DR ALLAN G BRAILEY This history leaves no room to doubt that this patient had liver disease of some type. The patient was an alcoholic of at least fifteen years' duration, and although she probably took more liquor than she admitted, the confessed intake accounted for some 1600 calories a day. Yet, during the previous year she had lost 25 pounds in weight, so that in all probability she did not consume much food other than alcohol and a serious protein deficiency must have been present. There is no final agreement regarding whether alcohol produces its harmful effect in liver disease solely by

astinal shadow The cough persisted and was intermittently productive of sputum, which was thick, yellow and tenacious, but not foul At about that time intermittent cramping lower abdominal pain and tenesmus developed, and frequent small stools, which sometimes contained blood, were passed Eight months before entry he was bronchoscoped three times at another hospital and was given penicillin and sulfonamides He improved, but fatigability prevented a return to work There was a weight loss of 25 pounds Three months before admission a barium enema showed an annular constricting lesion in the rectosigmoid region Proctoscopy revealed a fungating lesion 15 cm above the anal ring An x-ray film of the chest showed collapse of the left lower lobe, a paramediastinal mass and fluid in the left side of the chest. The symptoms persisted, and he had a feeling of discomfort in the left side of the chest

The patient's previous health had always been excellent A brother had died of Hodgkin's disease

Physical examination showed evidence of weight loss There was a triangular area of dullness at the left base posteriorly, with diminished breath sounds and tactile fremitus in this area There were no rales The liver edge was palpable 1 cm below the costal margin Fullness was palpable high in the rectum, but no definite mass was felt A hernia was present on the left above the inguinal ring

The urine contained a rare pus cell and an occasional red cell but was otherwise normal The hemoglobin was 9.5 gm, and the white-cell count was 5000 An x-ray film of the chest showed collapse of the left lower lobe with no change when compared to a film taken two months previously Sputum culture yielded a few alpha-hemolytic streptococci and a moderate growth of *Staphylococcus aureus*

The hospital course was uneventful A proctoscopic biopsy of the sigmoid lesion showed adenocarcinoma (Grade II), and a resection and end-to-end anastomosis were done Bronchoscopy was performed

DIFFERENTIAL DIAGNOSIS

DR W WILSON SCHIER My first reaction on reading this case was to obey the scientific principle of parsimony and explain the symptoms of cough, chest pain, hemoptysis, lower bowel obstruction and weight loss on the basis of one lesion — an adenocarcinoma of the rectum with metastases to the lung With further consideration I think that that is my second reaction as well

The striking feature is the association of chest symptoms with those of lower-bowel obstruction The first symptom to appear was the increase in the severity of a chronic cough in a fifty-six-year-old weaver His occupation suggests no predisposition to any disease Five months later the persistent

cough became severe, and the patient raised a little blood I assume from the history that he was hospitalized at about that time An x-ray film of the chest revealed atelectasis of the left lower lobe During the same period he also developed obstructive lower-bowel symptoms consisting of intermittent cramping pain and small, frequent, bloody stools On the last admission a biopsy of the rectal lesion demonstrated an adenocarcinoma (Grade II)

Three bronchoscopies had been performed at the time of the first hospital admission, eight months previously — no report is given, presumably nothing was found A weight loss of 25 pounds was noted

The history is comparatively short and consistent with that of a primary carcinoma of the lower bowel, with metastases to the left lung The metastases may have caused obstruction of the left lower-lobe bronchus by extrinsic pressure from invaded lymph nodes or lung parenchyma

DR STANLEY M WYMAN These chest films taken over a three-month period demonstrate the original collapse of the left lower lobe with the shadow lying behind the left border of the heart. The lung fields show no other evidence of active disease There is a small area of calcification in the extreme right apex The left hilus is depressed, and the left upper-lung field shows compensatory emphysema, in keeping with the collapse of the left lower lobe The grid film shows multiple areas of rarefaction in the left lower lobe consistent with the bronchiectatic cavities seen behind a blocked bronchus in chronic obstruction The left main bronchus can be traced only to a point just beyond the left upper-lobe branch No definite mass can be outlined, however Collapse seems to involve chiefly the apical portion of the left lower lobe, but there is probably some collapse of the base as well The left costophrenic angle is blunted posteriorly, but no definite fluid is seen During the period of observation the collapse becomes somewhat more pronounced, but again no definite mass can be outlined The heart shadow is not remarkable, and no definite destructive lesions are visible in the ribs The appearance is that of changes in the left lower lobe observed following prolonged obstruction to the bronchus, but no definite tumor is seen

DR SCHIER After seeing the x-ray films of the chest I cannot decide any more definitely the type of lesion that this man had During the course of the hospital stay there was further diminution in the size of the collapsed lower lobe If this had been a lymphomatous tumor one would expect to see large mediastinal masses Also, such a tumor would have had a faster course and evidence of spread elsewhere

The lesion in the rectosigmoid region was operated on at this hospital — probably as a palliative procedure Another bronchoscopy was also performed here, the results of which are not known The symp-

toms of chest pain and cough continued. These can be attributed to progressive obstruction of the left lower-lobe bronchus with pneumonitis and bronchiectasis beyond. It is not necessary to assume that a lung abscess was also present. The lack of foul sputum does not rule it out, for the alpha-hemolytic streptococci and the *Staph aureus* were associated with nonfoul lung suppuration. On the contrary, if fusiform bacilli and spirochetes had been present, the sputum would probably have been foul. Pneumonitis or extension of the tumor to the pleura could have caused the chest pain and accumulation of fluid seen in the chest x-ray film on admission. The low white-cell count is difficult to explain in the presence of lung infection.

The diagnosis of the lung disease hinges on the bronchoscopic findings — the obstructing lesion may have been missed on previous bronchoscopies because of surrounding granulation tissue. And it may have been missed here because of that. Primary lung disease cannot be ruled out. An adenoma is unlikely, for 7 out of 8 cases occur in women under forty years of age. This should be compared with carcinoma, in which 3 out of 4 cases occur in men and in which 5 out of 7 are in patients over forty years of age. The incidence of adenoma is 5 to 10 per cent of that of carcinoma, and five-year cures are obtained in over 95 per cent of cases. The five-year curability rate for resectable carcinoma of the lung is around 7 per cent. Other noncarcinomatous tumors of the lung, such as hamartoma and sarcoma, may have been present to cause the symptoms of bronchial obstruction. With these, as with dermoid cyst, I would expect a longer history of pulmonary difficulty.

Chronic lung infections of the granuloma type are to be considered in passing — that is, tuberculosis, fungus infections and syphilis. The last, of course, is extremely rare, and even if the blood Hinton reaction had been positive, I would not seriously consider it in this case. Infectious granulomas of the fungus type in the New England states can be confined to actinomycosis, and in the absence of a longer history, rural life and sinuses in the chest, I shall dismiss that diagnosis along with blastomycosis and histoplasmosis. Tuberculosis is a greater possibility both because of its incidence and because of the age and sex of the patient. The rate of pulmonary tuberculosis in women rises to a peak at the age of twenty-three, whereas in males — although less important at that age — it has a greater and rising incidence from the age of thirty-five on.

In the absence of more definitive sputum reports tuberculosis is still a possibility. Granulation tissue surrounding an endobronchial tuberculous lesion may hide such a lesion as it occasionally does with a primary bronchial tumor.

A noninfectious granuloma — Boeck sarcoid — should receive passing attention although obstructive bronchial lesions are unusual with this disease, and the patient's sex and age do not give this possibility any weight.

In summary, then, although a primary lung tumor or infection cannot be ruled out, I favor the diagnosis of a primary tumor in the rectum, with metastasis to the left lung.

CRITICAL DIAGNOSIS

Primary carcinoma of lung

DR SCHIER'S DIAGNOSIS

Adenocarcinoma of rectum, with pulmonary metastasis

ANATOMICAL DIAGNOSES

Adenocarcinoma of rectum
Squamous-cell carcinoma of lung

PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN. This patient had two separate cancers: an adenocarcinoma of the rectum and a squamous cell carcinoma of the lung. The latter diagnosis was made from the last bronchoscopy. The patient appeared to be in good condition, and a left pneumonectomy was performed. The specimen showed that the left lower-lobe bronchus was filled with white friable tumor, which had also extended up partially to occlude the lingular bronchus of the upper lobe. Beyond the obstruction the left lower-lobe bronchi were all dilated and thick walled. The surrounding pulmonary parenchyma was completely atelectatic and somewhat fibrous. Microscopically, it showed the chronic pneumonitis of the cholesterol type characteristic of chronic obstruction. Although the tumor had directly extended into two small lymph nodes within the lung, there was no evidence of metastases.

The patient did very well postoperatively, and the latest report, which was made only two months following the pneumonectomy, is that he was up and about and felt quite well.

SUBSCRIPTION TERMS \$6.00 per year in advance, postage paid, for the United States (medical students, \$3.50 per year), Canada, \$7.00 per year (Boston funds), \$8.50 per year for all foreign countries belonging to the Postal Union.

MATERIAL should be received not later than noon on Thursday, three weeks before date of publication.

THE JOURNAL does not hold itself responsible for statements made by any contributor.

COMMUNICATIONS should be addressed to the *New England Journal of Medicine*, 8 Fenway, Boston 15, Massachusetts.

OCTOBER MEETING OF THE COUNCIL

MUCH of today's discussion in medical circles concerns the various aspects of the trend toward the socialization of medicine and the development of prepaid medical care. This is, indeed, one of the major problems that confronts us. A large part of the debate in the Council meeting of October 1 took place over the resolution, already adopted by the Committee on Public Relations, "that the Blue Shield through its employees determine accurately an applicant's yearly earnings before issuing the policy, and secondly, that their earnings be reviewed each year." The cost and the difficulties of such a fact-finding program were pointed out, but a number of councilors had their say before the resolution was finally referred back to committee for further study, as the Executive Committee had recommended.

Progress in the organization of women's auxiliaries, under the experienced guidance of Dr. John F. Conlin, was reported, five districts having already approved the new suffrage. Some discussion took place over the action of the Committee on Public Relations in approving the objectives of the National Physicians Committee, but the report as a whole was accepted by the Council. The report of the Committee on Cancer approving the establishment of a cancer-detection clinic at the New England Deaconess Hospital was ordered tabled.

The Committee to Meet with General Hawley with the view of formulating a Program in Massachusetts for the Medical Care of Veterans and Their Dependents presented a *fait accompli* in the form of a neat contract with the Veterans Administration, already signed, providing for examination, treatment and counseling of eligible veterans in Massachusetts. This report was accepted without debate.

The colossal report of the Committee to Survey Malpractice Insurance in Massachusetts was accepted, and its four recommendations adopted; the report of the Advisory Committee on School Medical Services was referred back to the committee for further clarification.

The Committee to Study Special Hospital Services had labored during the summer and produced an almost unassailable report defining hospital services and medical services and establishing the proper relations between them. These relations will always be subject to change and revision with changing times and changing ideals. The Council recognized this report as covering present conditions and accepted it.

The matter of studying the Society's need of a full-time secretaryship and defining the duties of the Secretary, the Director of Medical Information and Education, and the Executive Secretary was referred to a committee of seven with power to act.

The reports of other committees were informational or self-explanatory.

An invitation from the Worcester District Medical Society to hold the annual meeting of the Society in Worcester in 1949 was accepted and referred to the Committee on Arrangements.

One still carries away from a Council meeting the wish that the functions of the Executive Committee might be better understood and employed. The purpose of the Executive Committee is to process the business of the Society before it is presented to the Council. If the Executive Committee does its work thoroughly and conscientiously, and if the councilors study the report of the committee, much of the debating time of the Council can be put to better advantage.

EPIDEMIC PLEURODYNIA

ELSEWHERE in this issue of the *Journal* appears a preliminary report of an outbreak of epidemic pleurodynia that occurred in Boston this summer. More than 100 cases clinically consistent with this diagnosis were seen at the Boston City Hospital alone. In addition, many members of the families of the patients are known to have suffered a similar ailment. In retrospect, many physicians will recognize this disease in many of the patients whom they have been called to see during the same period for unexplained febrile illnesses of various sorts. This is particularly true of household outbreaks involving multiple cases in which the illnesses began simultaneously or in rapid succession.

As usual in such epidemics, a number of cases have been confused with acute surgical conditions of the abdomen. Undoubtedly, some patients have been operated on unnecessarily because of the failure to consider epidemic pleurodynia in the differential diagnosis. An appreciable number, however, have been spared such operations at the Boston City Hospital and probably elsewhere because the physicians were aware of the prevalence of this condition. Some cases of this disease in which there were symptoms suggesting central-nervous-system involvement have probably been erroneously labeled benign lymphocytic meningitis or nonparalytic poliomyelitis. The latter disease is a particularly difficult one to differentiate during the summer months when both diseases are prevalent.

In patients with pleural pain or with pain referred to the abdomen, the diagnosis of epidemic pleurodynia should be entertained, and frequent examina-

tion of the chest for the presence of a friction rub should be made. Unfortunately, the diagnosis of this disease can be made only on clinical grounds, and the presence of a friction rub in the absence of pleural effusion or of pulmonary consolidation is the only reliable diagnostic sign now available.

The final report of the present outbreak and the results of attempts by several workers to isolate the causative agent will be awaited with interest.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

ALPERT — Louis Alpert, M.D., of Middleboro died on August 17. He was in his forty-fourth year.

Dr. Alpert received his degree from Boston University School of Medicine in 1929.

His widow and a daughter survive.

ARKIN — Louis Arkin, M.D., of Sharon, died on October 1. He was in his seventy-first year.

Dr. Arkin received his degree from Harvard Medical School in 1904. He was formerly professor of laryngology at Tufts College Medical School and was a member of the staffs of the Beth Israel Hospital and the Boston Dispensary. He was a member of the New England Otolaryngological and Laryngological Society and a fellow of the American Medical Association.

A brother and three sisters survive.

SAFFORD — M. Victor Safford, M.D., of Jamaica Plain, died on June 20. He was in his eightieth year.

Dr. Safford received his degree from Medical School of Maine, Portland, in 1893. He was formerly deputy health commissioner and epidemiologist, City of Boston Health Department.

His widow and a sister survive.

NEW HAMPSHIRE MEDICAL SOCIETY

DEATHS

DOLLOFF — Charles H. Dolloff, M.D., of Concord died on August 19. He was in his seventy-first year.

Dr. Dolloff received his degree from Dartmouth Medical School in 1903. He was appointed superintendent of the New Hampshire State Hospital in 1917. He was a member of the American Psychiatric Association and the New England Society of Psychiatry and was a fellow of the American Medical Association.

Two grandchildren survive.

FLYNN — Timothy P. Flynn, M.D., of Lancaster, died on September 1. He was in his fortieth year.

Dr. Flynn received his degree from St. Louis University School of Medicine in 1934. He served for two and a half years in the Army Medical Corps in World War II and was a fellow of the American Medical Association.

His widow, his mother, four children, a brother and two sisters survive.

SANBORN — Mary N. Sanborn, M.D., of Meredith died on September 6. She was in her eighty-fifth year.

Dr. Sanborn received her degree from College of Physicians and Surgeons, Boston in 1890.

Two sisters survive.

NOTE

The following New Hampshire physicians were recently appointed fellows in the American College of Surgeons: John H. Kennard, Manchester; Robert C. Nydegger, Concord; and Daniel J. Sullivan, Nashua.

MISCELLANY

MASSACHUSETTS TUBERCULOSIS LEAGUE

WHEREAS in the passing of Dr Robert N Nye the Massachusetts Tuberculosis League has lost an esteemed and most valuable friend as well as a member of its Board of Directors, and

WHEREAS in the passing of Dr Nye the League has lost a worthy representative of medicine and a most co-operative editor of the *New England Journal of Medicine*, therefore

BE IT RESOLVED That the Executive Committee of the Massachusetts Tuberculosis League, in session on September 18, 1947, expresses sincere regret at the untimely passing of Dr Nye, and

BE IT FURTHER RESOLVED that in behalf of the Massachusetts Tuberculosis League this Executive Committee extends sincere sympathy to Mrs Nye and other bereaved relatives, as well as to the associates in medicine of Dr Nye and to his associates in the *New England Journal of Medicine* and

BE IT FURTHER RESOLVED that a copy of these notes be sent to Mrs Nye, to the president of the Massachusetts Medical Society and to the *New England Journal of Medicine*

CLEAVELAND FLOYD

NOTICES

NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children will be held on Thursday, November 6, at 7 15 p m in the classroom of the Nurses' Residence. The subject "Dizziness and Vertigo," with lantern slides, will be discussed. Dr Madelaine R Brown will be chairman.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

On Wednesday, November 12, the Division of Hospital Survey and Construction of the Massachusetts Department of Public Health will hold a public meeting to present the State Plan for administering Public Law 725 (Hospital Survey and Construction Act) in the Gardner Auditorium, State House, Boston, at 2 00 p m. The subjects and speakers are as follows:

Explanation of Public Law 725 — Hospital Survey and Construction Act. Vlado A Getting, M D, commissioner, Massachusetts Department of Public Health.

A Plan for the Administration of Public Law 725 in Massachusetts. Staff members of the Division of Hospital Survey and Construction, including A Daniel Rubenstein, M D, director, Claire F Ryder, M D, epidemiologist, Mr Arthur V Harrington, senior engineer, and Mr William W Wood, survey administrator.

Hospital administrators, local health-department officials and all other interested persons are invited to attend.

JOHN AND MARY MARKLE FOUNDATION GRANTS

The John and Mary Markle Foundation has announced a new program of "post-fellowship grants" by means of which young scientists with the necessary training to hold regular faculty appointments and to conduct original research are offered an opportunity to start a career in academic medicine. Candidates will be recommended by accredited medical schools in the United States and Canada, which will determine the appropriate salary and academic rank, encourage research by setting reasonable limits on teaching and other nonresearch activities, provide laboratory facilities and, if necessary, make financial contribution to the support of the

work. Regional committees appointed by the Foundation will make the final selection of candidates on the basis of the recommendation of the medical schools. Grants of \$25,000, payable to the co-operating school at the rate of \$5000 annually for a five-year period, will be available beginning with the academic year 1948-49. No fixed number of candidates will be appointed in any year, but it is expected that approximately fifty will receive appointments during the five-year period. Details of the program have been sent to all deans of accredited medical schools, to whom those interested in being considered as candidates should apply for further information.

NEW ENGLAND EPILEPSY LEAGUE

Announcement of the incorporation of the New England Epilepsy League was recently made by L Sherrill Bigelow, president. This organization is a non-profit, self-supported affiliate of the American Epilepsy League, Inc., which has moved to Chicago. The League is governed by a volunteer board of directors, working in close co-operation with a medical advisory board. The program of the League is primarily one of education and referral. The referral service includes lists of physicians, hospitals and clinics particularly interested in the care and treatment of epileptic patients, special schools for the education of children with seizures, colleges and universities that will accept epileptic students and information on training opportunities for the adult epileptic patient provided by state and private agencies. Medical reprints and articles written on the various phases of problems faced by the epileptic, his family and friends are available to all professional and lay members of the New England Epilepsy League. In addition to the above mentioned pamphlets, Dr. William G Lennox's book *Seizures and Seizures* is given each member. The officers of the League are anxious to bring information about new methods of treatment to the physicians of New England, who are urged to call on the League at any time. Communications should be addressed to Miss Esther C Walther, director, New England Epilepsy League, Inc., 50 State Street, Boston 9 (Telephone LAfayette 2550).

UROLOGY AWARD

The American Urological Association offers an annual award of \$1000 (first prize of \$500, second prize \$300 and third prize \$200) for essays on the result of some clinical or laboratory research in urology. Competition is limited to urologists who have been in such specific practice for not more than five years and to residents in urology in recognized hospitals. All interested should write to the secretary, Dr Thomas D Moore, 899 Madison Avenue, Memphis, Tennessee. Essays must be in his hands before March 1, 1948. The first-prize essay will appear on the program of the forthcoming meeting of the American Urological Association, to be held at the Hotel Statler, Boston, May 17 to 20.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING THURSDAY, OCTOBER 30

FRIDAY, OCTOBER 31

*9 00-10 00 a m. Precautions in Handling Radioactive Materials in Medical Research. Dr Shields Warren. Joseph H Pratt. Dorchester Hospital.

*10 00 a m-12 00 m. Medical Staff Rounds. Peter Bent Brigham Hospital.

MONDAY, NOVEMBER 3

*12 15-1 15 p m. Clinicopathological Conference. Peter Bent Brigham Hospital.

TUESDAY, NOVEMBER 4

*12 15-1 15 p m. Clinicorontgenological Conference. Peter Bent Brigham Hospital.

WEDNESDAY, NOVEMBER 5

*12 00 m. Grand Rounds and Clinicopathological Conference (Children's Hospital). Amphitheater. Peter Bent Brigham Hospital.

*2 00-3 00 p m. Combined Clinic by the Medical Surgical and Orthopedic Services. Amphitheater, Children's Hospital.

*Open to the medical profession.

THE DIAGNOSTIC AND THERAPEUTIC VALUE OF LIVER BIOPSIES*

With Particular Reference to Trocar Biopsy

WADE VOLWILER, M.D.,† AND CHESTER M. JONES, M.D.‡

BOSTON

ACCURATE information regarding the particular phase of any morbid process under observation is essential to the institution of adequate therapeutic measures. Such an obvious and desirable goal, until recent years, has been only vaguely obtainable in intrahepatic disease. Numerous liver-function tests of simple or complex nature have been devised but have proved useful primarily as a means of estimating the degree of functional damage and of following the progress of intrahepatic disease rather than as a measure of exact diagnosis. The multiplicity of the liver's functions and its notable reserve capacity are such that at best, even when the entire battery of laboratory studies is employed, an imperfect set of findings is obtained. This statement is not to be interpreted as underestimating the various tests of hepatic function, which have a distinct but limited value.

For these reasons various investigators have made an effort to obtain exact histologic information by means of liver biopsy. We also have been interested in a careful histopathologic study of liver disease and have found, as others have, that such knowledge is frequently vital in making correct clinical decisions regarding the differentiation of intrahepatic and extrahepatic biliary obstruction, the type of intrahepatic disease present, the stage of a known intrahepatic disease, the specific therapeutic program to be followed and the appraisal of a therapeutic regime. To justify the practice of liver biopsy, it is necessary to satisfy the following conditions: the procedure must present no undue risk to the patient, and the material so obtained must be adequate for careful histologic examination.

In general, all three of the present-day methods (laparotomy with small incision under local anesthesia, peritoneoscopy and needle biopsy) fulfill both these requirements. Laparotomy is usually

unjustified if either of the two other procedures is available, since the discomfort to the patient is as great as that in the usual peritoneoscopy and the abdominal-wall incision is necessarily much larger. The area of hepatic tissue grossly visualized in such a laparotomy is, of course, considerably less than that seen through the peritoneoscope. In terms of time and money, the expense to the patient is greatest for laparotomy and least for trocar biopsy.

Peritoneoscopy is a painful procedure, and it is therefore difficult to induce a patient to have a second or third examination to obtain material useful in following the progress of intrahepatic disease. In diffuse liver disease, a peritoneoscopic biopsy is often inadequate in its sampling of tissue, and when there has been intrahepatic scarring, the specimen may consist chiefly of liver capsule. Peritoneoscopy should be chosen as a rule when a search for a focal lesion—for example, a neoplasm—is necessary. Even in diffuse intrahepatic disease gross visualization of the liver at times adds important information to that obtained histologically; often, this can all be accomplished by a single peritoneoscopic examination. This procedure also enables the operator to coagulate electrically the site of biopsy if much bleeding is seen. The use of an exterior biopsy needle combined with peritoneoscopy^{1, 2} seems unnecessarily elaborate except in unusual circumstances.

Needle biopsy of the liver, when properly performed, usually causes little discomfort and, if a fairly uniform pathologic process is present, provides a satisfactory sampling of tissue from deep within the liver substance. The development of this method has previously been adequately discussed.³⁻⁵ If the liver is markedly enlarged, an attempt to obtain a specimen of suspected metastatic neoplasm by needle biopsy is often reasonable, but failure to find it by this blind method in no way rules out that diagnosis. In coarsely nodular, "toxic cirrhosis," a needle biopsy may fail to include scar tissue although the specimen is seemingly sufficient in amount. Trocar biopsy of a liver that is

*From the Medical Service, Massachusetts General Hospital, and the Department of Medicine, Harvard Medical School.

†Assistant in medicine, Harvard Medical School; assistant in medicine, Massachusetts General Hospital.

‡Clinical professor of medicine, Harvard Medical School; physician, Massachusetts General Hospital.

considerably smaller than normal is, in our experience, uncertain and unsafe, nor should a biopsy needle be thrust blindly across pleural or peritoneal planes when focal suppuration is suspected. Chronic passive congestion of the liver may contraindicate liver biopsy, although we have obtained without untoward incident a trocar biopsy in 4 such cases and Sherlock⁷ reports 25 cases.

METHOD

Experience has indicated that, if proper biopsy material is to be obtained consistently, a special kind of needle is necessary. Of the various types of biopsy needles used at present, one is about as satisfactory as another if the operator is experienced and skillful. For the study of most hepatic disorders, we have chosen to use an American modification of the Iversen-Roholm needle, known as the Franseen biopsy needle,* because it seems to be the simplest effective apparatus available for this purpose. It differs from the original one described by Iversen and Roholm⁹ only in that the three sharp points have been fully developed into three sharp teeth. We use the No. 14 gauge size, 11 cm. in length.

The biopsy is performed at the bedside with the patient lying flat on his back, the anterior approach is used. The skin is prepared with alcohol and iodine, and a sterile sheet with a central hole is placed over the chosen area. After a skin wheal has been made with novocain, the thoracic or abdominal wall down to and including the peritoneum is rapidly anesthetized while the patient holds his breath in the phase of respiration chosen for the biopsy. A 0.3-cm. skin nick is made with a sharply pointed Bard-Parker blade. The patient hyperventilates a few times and holds his breath while the biopsy is being done. The biopsy needle, stylet in place, is quickly pushed through all layers of the abdominal wall to the surface of the liver capsule. The stylet is withdrawn and the needle shaft rapidly advanced within the liver substance for a vertical distance of 3 or 4 cm. Suction is then applied to the end of the needle with a 20-cc. syringe having a metal adapter. With the suction in place, the needle and syringe together are quickly withdrawn. As this is done, the tissue obtained usually slides up the needle shaft into the barrel of the syringe, and immediately 10 cc. of physiologic saline solution is aspirated into the syringe to prevent a blood clot from forming around the biopsy specimen. The tissue is then transferred to the fixative.

The actual biopsy maneuvers must be accomplished within ten seconds to allow the patient to hold his breath and lie immobile, otherwise, a liver tear is possible. Overbreathing to achieve a period of spontaneous apnea helps the patient fulfill this requirement. We believe that there should be no fixed rule concerning the site of biopsy, which should be chosen by the operator in each case according to the

physical examination. By the anterior approach, if the liver is enlarged, either the right or the left lobe may be chosen, provided a 5-cm. margin of safety lies between the site of biopsy and the lower liver edge. If the lobe is sharp-edged and thin, the needle should be pointed obliquely cephalad to prevent puncture of organs on the opposite side. An appreciable ascites should be tapped prior to the procedure. If the liver is only minimally enlarged or is of normal size, it is unsafe to attempt biopsy below the costal margin. In such a case, one may proceed with care transpleurally in the anterior axillary line through the intercostal space during expiration. The space usually chosen by us is the first or second below the top level of liver dullness. We prefer to risk going too high rather than too low since, if the patient is immobile, no harm results from puncturing the lower thin edge of lung.

The patient must be alert and co-operative. The prothrombin time must be carefully checked and should be within normal limits or only slightly prolonged. In unusual cases, a freshly drawn, citrated whole-blood transfusion may be given just prior to the biopsy to reduce temporarily an elevated prothrombin time that has been resistant to parenterally administered vitamin K derivatives. An intramuscular injection of one of these derivatives should be given routinely two hours before the biopsy, regular prebiopsy cross matching for possible later transfusion seems unnecessary.

Pain following needle biopsy is highly variable and unpredictable. It is undoubtedly due to irritation of the serous surfaces by extravasated blood. Biopsies done by the trocar method under direct observation at laparotomy produce from 5 to 20 cc. of blood from normal livers. Pleural pain is almost always present after the use of the intercostal approach, but it is usually not severe after the first half hour. It is considered wise to give parenteral Demerol and an oral salicylate routinely half an hour before the biopsy. The patient should lie quietly in one position for the first hour following the procedure, and should stay in bed for the subsequent twenty-four hours. The return of pain after ambulation is a warning sign of probable further oozing of blood from the biopsy site, and if this occurs the patient should immediately return to bed for at least twenty-four hours longer.

RESULTS

We have attempted needle liver biopsy by this method 234 times in 191 different patients. Of these, 216 biopsies, obtained from 174 patients, provided tissue sufficient for adequate histologic appraisal. In 5 cases focal lesions were missed by an apparently satisfactory biopsy. Sixty-eight biopsies were performed transthoracically in patients with livers of normal size. Thirty-two patients were examined serially with from 2 to 6 biopsies each during the course of therapy. The distribution of pathological

diagnoses in this series is shown in Table 1. Most of the unsuccessful biopsy attempts occurred in patients with ascites that had not been tapped, or in cases of far-advanced fibrosis in which the suction was apparently insufficient to extract the laterally severed tissue from its base.

One death from uncontrolled hemorrhage followed trocar liver biopsy. In this case the biopsy of a large amyloid liver was accomplished with ease while the patient lay immobile. Hykinone had been given parenterally before biopsy. The prothrombin time was 6 seconds prolonged, which is the arbitrary limiting value chosen by us for this procedure. Ten hours later the patient was found in shock after several hours of severe abdominal pain. Post-mortem examination two days later showed that the needle had pierced the right main hepatic vein 4.5 cm from the surface of the capsule. Intrahepatic bleeding appeared to have created enough pressure to split the fragile, superficial amyloid liver tissue, forming a huge laceration extending the entire vertical length of the right lobe. This rent had extended much farther during the twenty-four hours after fibrin foam packing at surgical laparotomy.

One patient died with peritonitis that was possibly attributable to the biopsy procedure. This man, with a fulminating acute cirrhosis, was found at autopsy to have a beta-hemolytic streptococcus peritonitis and septicemia. The pathologist stated that this infection appeared to be of three to ten days' duration. The temperature chart and clinical data provided no clue to the time of its onset. The biopsy had been performed five days before death. Since this experience, all biopsy instruments have been carefully autoclaved as complete sets. We believe, however, that this death was not attributable to aspiration biopsy.

Moderate bleeding after biopsy was observed in 3 other patients, in all of whom the prothrombin time was normal, none required transfusion. Two patients bled intra-abdominally, accumulating a detectable ascites, and 1 developed a large abdominal-wall hematoma without intraperitoneal bleeding. One of those with intraperitoneal bleeding had a highly vascular metastatic carcinoma, the other had shown a slight hemorrhagic tendency, not related to platelet or vitamin C lack, but had been given a fresh whole-blood transfusion just before the biopsy.

CASE REPORTS

The following cases illustrate the value of liver-biopsy material in providing correct diagnoses, in determining the phase of a given hepatic disorder actually present and in appraising the results of a therapeutic program in patients with diffuse liver damage.

CASE 1. A thin, tired 48-year-old man was hospitalized for study of painless, pruritic, deep jaundice that had been present for 3 weeks. This had been preceded by 3 months of increasing fatigue and a weight loss of 20 pounds without gastrointestinal symptoms. No history of alcoholism was obtainable. The jaundice had been accompanied by light stools and dark urine. A slightly enlarged, nontender liver was palpable. No splenomegaly, spider angiomata or abnormal fluid retention was demonstrable. A dry films of the chest and upper gastrointestinal tract were normal. During the 1st week of hospitalization the stool varied irregularly from clay colored to light brown. One stool was strongly guaiac positive. Two sets of blood chemical studies a week apart were almost identical in values including a total serum bilirubin of 40 mg. per 100 cc., a serum alkaline phosphatase of 9 Bodansky units and a total cholesterol of 255 mg. per

100 cc. with normal figures for prothrombin, thymol turbidity and flocculation, cephalin flocculation, albumin and globulin.

Because metastatic carcinoma was strongly suspected, a peritoneoscopy was performed. No focal lesions were seen. The specimen obtained on liver biopsy was typical of epidemic infectious hepatitis, which had not been suspected from the clinical and laboratory data (Fig. 1). In this case an exploratory laparotomy that might have impaired or greatly retarded the patient's recovery was avoided.

CASE 2. A drowsy, well nourished 69-year-old man presented a history of an acute painless illness of 3 weeks duration, initiated by abdominal distention and vague indigestion. This was followed in 2 weeks by nausea, vomiting, fatigue and dark urine. Three days before entry frank jaundice had appeared.

Moderate icterus and a large, symmetrical, slightly tender liver were the only abnormal physical signs present. The stools were brown.

Laboratory studies included a cephalin flocculation test, which was +++ in 24 hours, a serum alkaline phosphatase of 12 Bodansky units per 100 cc. and a positive test for urinary urobilinogen in a dilution of 1:512.

Some observers believed this to be a fulminating acute epidemic infectious hepatitis, superimposed on a large, fatty or cirrhotic liver although no reliable history of alcoholic intake could be extracted. Others held that such a tremulous, firm liver ought to be filled with neoplasm. A needle biopsy of the liver demonstrated a malignant lymphoma (Fig. 2).

At post mortem examination this process was seen to be localized to the liver, vertebral bone marrow and mesenteric lymph nodes. A correct ante-mortem diagnosis could have been made only by liver biopsy.

CASE 3 A cachectic, 63-year-old man had been seen in the outpatient clinic 6 weeks before admission complaining of migratory bone and joint pains. A careful and complete physical examination at that time had been negative. X-ray films of the chest and various bones were normal. Two weeks before entry, there was a rapid onset of ankle edema, chest and back pain and alternate constipation and diarrhea. Physical examination showed fluid in the right pleural cavity, ascites, peripheral edema and hepatomegaly. X-ray films of the colon, upper gastrointestinal tract and kidneys were normal. It was assumed that widespread metastatic neoplasm was present. A peritoneoscopy was performed by Dr Edward B. Benedict, whose report was as follows:

The surface of the left lobe is smooth, with a slightly rounded edge and a 0.5-cm lesion on the lower part of the anterior surface. This lesion may be metastatic carcinoma but could be fibrosis. The right lobe is smaller than the left, a little more irregular and slightly granular, with a more rounded edge. There are no areas on the sur-

and that for 17-ketosteroid urinary excretion showed 18 mg in 24 hours. X-ray films revealed no esophageal varices. A skin test with acidified potassium ferrocyanide solution and two skin biopsies were negative for hemachromatosis. A trocar liver biopsy showed definite hemachromatosis (Fig 4). The patient returned to the hospital 1 month later in cardiac failure and died, and autopsy disclosed hemachromatosis of the liver, pancreas, adrenal glands, lymph nodes, thyroid gland, pituitary body and heart. Esophageal varices were also present. Liver biopsy was essential for a correct clinical diagnosis in this case.

CASE 5 A middle-aged man was admitted to another hospital* because of chronic alcoholism of 3 years' duration. For the 3 weeks before entry he had ingested little food but considerable alcohol. When completely sober, he maintained that he had no symptoms of any physical illness what-

face suggesting carcinoma. In the lower portion of the abdomen on the peritoneal surface of the abdominal wall there are three or four gray-white, irregular areas about 1 cm in diameter that look fibrotic but may be metastatic carcinoma. None of them are sufficiently large or accessible enough for biopsy. In a biopsy specimen taken from the anterior surface of the left lobe of the liver, the capsule is extraordinarily tough, and it is quite possible that little liver tissue was obtained. It was impossible to take the biopsy from the small lesion where carcinoma was suspected because this area could not be found with the small telescope. The findings are inconclusive. From the size of the liver and the appearance of it, there may be carcinoma inside the capsule that has not yet broken through and is therefore not visible by peritoneoscopy, although there is a slightly suspicious area.

The biopsy so obtained consisted of a small island of normal liver cells. A few days later a trocar biopsy was obtained from both the right and the left lobes of the liver, each specimen consisted almost entirely of carcinoma, interpreted by the pathologist as suggestive of hepatoma (Fig 3).

It is unusual for a blind needle biopsy to yield neoplastic tissue when the peritoneoscopy has failed to obtain it.

CASE 4 A 45-year-old man developed progressive hepatic enlargement during the 2 years subsequent to a transient episode of icterus that occurred during antisyphilitic arsenical therapy. He was a frequent imbibor of alcohol. Physical examination revealed diabetes, a large liver and a slight tan tint to the skin. Splenomegaly, edema, icterus and spider angiomas were absent. Laboratory data included a negative cephalin-flocculation test, a total serum protein of 6.8 gm per 100 cc, with an albumin of 3.2 gm, a globulin of 3.6 gm and an alkaline phosphatase of 3.2 Bodansky units per 100 cc. The brom-sulfalein test showed 22 per cent retention of the dye in 45 minutes after a dose of 5 mg per kilogram of body weight. The blood electrolytes were normal, a test for follicle-stimulating hormone was positive for 6.5 mouse units in 24 hours,

soever, although the liver was large and the scleras slightly icteric. He was afebrile. Laboratory data revealed a trace of bilirubinemia and urine urobilinogen detectable in a 1:1500 dilution. The brom-sulfalein test showed 36 per cent retention of the dye in 45 minutes after a dose of 5 gm per kilogram of body weight. The serum bilirubin was 0.8 mg per 100 cc direct and 1.5 mg indirect. The values for serum albumin, globulin, prothrombin, vitamin A, cephalin flocculation and thymol turbidity and flocculation were normal. A trocar liver biopsy obtained was described as follows: There is severe diffuse cirrhosis with unusually marked polymorphonuclear infiltration. Fat vacuolization is of moderate severity and irregularly distributed. The vacuoles are of exceptional size. In a few areas hyaline degeneration is evident (Fig 5).

This severe, acute, degenerative process had been unsuspected by careful clinical and laboratory examinations. Because of the histologic information, the patient was kept under close medical observation and given intensive dietary therapy. A second biopsy was obtained 3 weeks after the first, at which time the liver was only slightly smaller. The patient was still minimally icteric, although bile pigment had disappeared from the urine. The urinary urobilinogen had returned to a normal concentration, the other liver-function tests were essentially unchanged. Histologic comparison of this biopsy with the first showed a marked reparative change to have taken place.

The fat has largely disappeared. The majority of the liver cells now appear normal, whereas few did so in the original biopsy. Polymorphonuclear cells are still present, but markedly decreased in number. The fibrosis remains unchanged (Fig 6).

In the following patients with similar clinical histories, physical findings and laboratory tests, histologic studies of the liver were markedly different. On physical examination the livers were

*This patient was examined through the courtesy of Dr Joseph Thimann, medical director of the Washington Hospital, Boston, an institution devoted to the treatment of male alcoholic patients.

approximately of the same size, and icterus was not evident. The laboratory data in these cases are presented in Table 2

CASE 6 A 46-year-old man was admitted to the hospital because of a rapid onset of ascites within a few days. For many years the alcoholic intake had been impressive, and the food intake scant and irregular. Ankle edema had been present intermittently for 6 months.

Physical examination revealed spider angiomas, ascites, ankle edema, splenomegaly and an enlarged firm liver.

A liver trocar biopsy obtained shortly after admission was described as follows:

A definite cirrhosis without fat vacuolization is seen. Many liver cells show pyknosis. Hyaline bodies thought to represent remnants of necrotic liver cells are present. There is moderate lymphocytic infiltration of the portal areas.

This fibrotic inflammatory picture was not considered characteristic of either the usual and expected degenerative cirrhosis associated with malnutrition and alcohol or the epidemic infectious hepatitis due to a virus. A satisfactory pathological classification was impossible.

CASE 7 A 35 year-old Italian housewife was admitted because of anorexia, weakness and abdominal swelling of 3 months duration. For many months the food intake had been exceedingly poor in quality and small in quantity. The regular daily intake of wine had progressively increased.

Physical examination demonstrated a minimal ascites, a large liver and a palpable spleen.

Needle liver biopsy obtained shortly after admission was reported as follows:

The architecture is obliterated and there is definite cirrhosis. There is abundant fat, a small amount of hyaline degeneration and scattered focal necroses with considerable polymorphonuclear reaction.

This was considered typical of the acute inflammatory degenerative cirrhosis usually associated with malnutrition and alcohol.

CASE 8 A 45 year-old woman with a prolonged copious alcoholic and poor food intake was hospitalized because of ascites of a few weeks duration. Physical examination showed moderate ascites, a large liver and a smooth red tongue.

Needle liver biopsy revealed a histologically stationary portal cirrhosis with nodular parenchymal cell regeneration and fibrosis, without active inflammation, fatty infiltration or cellular necrosis.

Discussion

The differentiation of intrahepatic and extrahepatic biliary block in a case of icterus often poses a difficult problem for the clinician. Clinical facts and a complete set of liver-function tests may be initially inconclusive, whereupon one is faced with the choice of three alternatives: immediate exploratory laparotomy, further observation until such time as the diagnosis becomes clinically obvious and liver biopsy by the peritoneoscope or by trocar. Even under local or spinal anesthesia, abdominal exploration often produces a serious exacerbation of an intrahepatic inflammatory process and is to be avoided if possible. During the course of one or two weeks' hospitalization, clinical and laboratory findings may clearly indicate an intrahepatic or extrahepatic biliary block, but indefinite drifting without a clinical solution to the problem is undesirable. Biopsy material obtained early in the course of hospitalization will prevent

uncertainty and may save time that is therapeutically valuable, as in Case 1 above.

Biopsy may also provide the only reliable information regarding the kind of intrahepatic disease present, as in Cases 2, 3 and 4. Liver-function tests and clinical data may promptly indicate intrahepatic impairment but may give only a vague idea of its nature. An exacerbation of degenerative cirrhosis with icterus is often mistaken for epidemic infectious hepatitis. Hemachromatosis without diabetes or skin pigmentation may masquerade as ordinary cirrhosis. By liver aspiration biopsy we have found other diseases clinically unsuspected, including amyloid infiltration, sarcoid, lymphoblastoma, aleukemic leukemia and carcinoma. By this method a neoplasm was obtained from deep within both enlarged hepatic lobes in 2 patients in whom peritoneoscopy had failed to demonstrate a surface lesion. Case 3 was one of these, and in the other a biopsy taken at laparotomy had also been normal. Sufficient parenchymal-cell regeneration may occur to compensate fully for a degenerative cirrhosis, so far as laboratory measures of function are concerned, even though the fibrosis present may cause venous portal hypertension. When laboratory function tests are completely normal, biopsy alone will solve the cause of hepatic enlargement.

If one is to know accurately the phase of a recognized diffuse intrahepatic disease (with the exception of simple, acute epidemic virus infectious hepatitis), liver biopsy is usually necessary. In prolonged, chronic epidemic infectious hepatitis, liver-function studies may give only a rough idea of the degree of active inflammation, cellular degeneration and fibrosis present.¹⁹ Severe, acute "alcoholic cirrhosis" may exist without notable symptoms or marked derangement of laboratory and liver-function tests, as in Case 5. All cases of cirrhosis do not present a uniform histologic picture. Striking differences in the degree of cell necrosis, inflammatory reaction, fat vacuolization, fibrosis and liver-cell regeneration may be seen in patients with identical clinical findings and liver-function tests (Cases 6, 7 and 8). In such cases the immediate clinical response to be expected from strenuous therapy and the long-term prognosis may be indicated by the histologic state of the liver at the time treatment is instituted. Obviously, little improvement can be expected with an end-stage, stationary histologic picture, such as that in Case 8, whereas a far better prognosis is indicated by the active processes of reparative regeneration usually observed in the acute degenerative fatty livers associated with alcohol and malnutrition (Cases 5 and 7).

Liver biopsy material may provide, in addition, important indications for a specific therapeutic program. Supplements of lipotropic substances will be used with considerably more enthusiasm if appreciable fat vacuolization of the hepatic cells is observed, particularly if it is present after a pro-

longed and adequate dietary regime has been followed. Since the severity of active intrahepatic necrosis and inflammation often does not correlate with the clinical impression, as in Cases 5, 6, 7 and 8, in chronic infectious hepatitis of long duration and in degenerative cirrhosis, the obtaining of biopsy material may sometimes show the necessity for a more intensive and careful therapeutic program than would otherwise be pursued. In considering the propriety of a Blakemore surgical attack on portal hypertension by venous anastomosis in a patient with cirrhosis, a study of liver histology is desirable to rule out active intrahepatic degeneration. Its presence increases the operative risk and demands a preoperative preparation of several weeks' dietary treatment. On the basis of a diagnostic liver biopsy, specific therapy may be determined for conditions such as kala-azar, schistosomiasis, tuberculosis, syphilis, leukemia and lymphoma.

Finally, in certain types of diffuse intrahepatic disease, biopsy material is absolutely essential to accurate appraisal of the results of a therapeutic program. As a supplement to clinical and laboratory information, histologic data are particularly necessary in evaluating the various methods of treating degenerative cirrhosis and fatty liver. During the course of treatment of an acute exacerbation of cirrhosis, laboratory tests frequently give a false impression of the phase of the degenerative inflammatory process actually present, as in Case 5 above. In the face of unchanged, poor hepatic function, as measured by serial laboratory examinations, a satisfactory decision regarding when to mobilize the patient and cease heroic care may depend on biopsy findings.

In our experience, the needle aspiration biopsy method described above has been satisfactory for obtaining an optimal sampling of liver histology in patients with diffuse hepatic disease. By this procedure, trauma and maceration of the biopsy tissue have rarely been troublesome. Its very simplicity encourages its wide application as a tool for the study of abnormal physiology in disease of the human liver and as a method for making exact pathological diagnoses. To a large degree, the risk will depend on the experience and judgment of the operator and on the accuracy of the physical examination, not all patients are suitable candidates. Our mortality to date (0.5 per cent), our minimal incidence of other complications and the mortality for other published trocar liver biopsy series^{6, 7} compare favorably with reported peritoneoscopic statistics¹¹⁻¹³ for which Benedict¹¹ estimates the mortality should be less than 1 per cent. It is believed that the value of the histologic information to be gained by needle aspiration biopsy more than justifies the small risk involved.

SUMMARY

The technic and indications for use of needle aspiration liver biopsy are described.

We have performed 234 such procedures with 0.5 per cent mortality. Of the total number, 216 provided sufficient tissue for adequate histologic appraisal, in 79 cases the biopsy was essential to an accurate clinical diagnosis.

It is believed that aspiration liver biopsy will furnish the following practical information: correct differentiation of extrahepatic and intrahepatic biliary obstruction when clinical and laboratory data are inconclusive, exact diagnosis of the type of diffuse intrahepatic disease, determination of the particular phase of a known subacute or chronic hepatitis present, indications for therapy not obtainable from complete clinical and laboratory examinations, and accurate evaluation of therapeutic regimes in certain types of chronic hepatic disease.

In our experience, needle aspiration liver biopsy has proved a useful and safe measure for making exact diagnoses and for studying the abnormal physiology of liver disease.

Since this report was submitted for publication, we have attempted needle aspiration biopsies of the liver in 44 additional cases, in 43, satisfactory tissue specimens were obtained. Three further nonfatal complications were encountered: massive intra-abdominal hemorrhage requiring transfusion occurred in a patient with a normal prothrombin time (autopsy many weeks later disclosed a large subcapsular hematoma of the liver), during a transpleural biopsy approach, 15 cc of clear bile was aspirated from a gall bladder, but no liver tissue was obtained — recurrent pain and fever during the subsequent ten days, indicating a mild right upper-quadrant bile peritonitis, subsided spontaneously, and atelectasis of the lower lobe of the right lung occurred one day after biopsy of an enlarged liver through an abdominal approach — this pulmonary collapse was presumably produced by splinting of the right leaf of the diaphragm because of severe pain following the biopsy.

RENAL DAMAGE FOLLOWING INTRAVASCULAR HEMOLYSIS*

E LANGDON BURWELL, M.D.,† THOMAS D KINNEY, M.D.,‡ AND CLEMENT A FINCH, M.D.§

BOSTON

THE sequence of hemoglobinuria followed by oliguria and anuria is well known. The observations reported below are especially concerned with the medical management of the anuric patient and with the functional and anatomic reversibility of the renal lesion produced.

In the case of anuria following massive intravascular hemolysis reported below, the patient recovered from the episode only to succumb three months later to homologous serum hepatitis. During the intervening period, the renal function showed steady improvement as evidenced by clinical and laboratory tests. Autopsy offered a unique opportunity to correlate the residual anatomic lesions with the clinical picture. In a review of the literature, no similar observation was encountered, the pathological data reported being limited to the acute phase of the condition.

CASE REPORT

B. H., a 29 year-old housewife was admitted to the hospital because of anuria. During the week prior to admission an abortion had been performed at the 4th or 5th month of pregnancy, and the patient subsequently had vaginal bleedings. Three days before entry it was noted that she was pale and that the skin was 'throned'. She became weak and delirious, and was taken to another hospital, where she was unresponsive and apparently in shock. The red-cell count was recorded as 750,000, and the blood was Type A and Rh+. No difficulty was encountered in typing or cross matching, but it was noted that the patient's blood was badly hemolyzed. A 500-cc. transfusion of Group A Rh+ blood was given. Since the patient had not voided since admission, she was catheterized several hours after completion of the transfusion and 30 cc. of dark-brown urine full of amorphous material was obtained. She was then transferred to the Peter Bent Brigham Hospital.

There was no history of nephritis or any indication of previous renal damage. The patient had had an earlier pregnancy resulting in a full-term normal delivery of a healthy male infant 10 months prior to admission. There was no past or family history of anemia, jaundice or blood disorder.

Physical examination disclosed a delirious and nonresponsive patient. The face was puffy, and there was a bluish-brown tint to the skin. The sclerae were dull and questionably icteric. There were several hemorrhages in the fundi. The mucous membranes were exceedingly pale. Examination of the chest was negative. The heart was normal in size, and the rate rapid and regular, with occasional extra systoles and a Grade I apical systolic murmur. The abdomen was slightly distended. The liver and spleen were not palpable. The legs showed barely perceptible edema. Neurologic examination was negative. Pelvic examination revealed a soft boggy cervix with a widened os and some discharge from it. The uterine fundus was two or three times the normal size. There were no adnexal masses.

Examination of the blood revealed a hemoglobin of 4.4 gm., with a hematocrit of 10 per cent, and a white-cell count

of 41,900 with 76 per cent neutrophils, 15 per cent young granulocytes, 4 per cent lymphocytes and 5 per cent monocytes. There were marked spherocytosis (Fig. 1) and autoagglutination and a reticulocyte count of 5.1 per cent. The fragility of the red cells to hypotonic saline solution was increased. The platelets appeared normal on smear. The serum was dark reddish brown in appearance and on the following day contained 222 mg of hemochromogens per 100 cc., most of which was in the form of free hemoglobin (Table 1). A blood Hinton test was negative. Twenty cubic centimeters of urine obtained by catheterization was reddish brown, with a reaction of pH 7.5. The urine showed a +++ test for protein, no sugar and a positive test for bilirubin and also for hemoglobin, and the sediment contained rare red cells, many white cells and a large amount of amorphous material.

The blood urea nitrogen was 170 mg., the nonprotein nitrogen 270 mg. and total protein 6 gm. per 100 cc. with 3 gm. of albumin and 3 gm. of globulin. The fasting blood sugar was 131 mg. per 100 cc., and the carbon dioxide combining power was 15.2 and the blood chloride 110 milliequivalents per liter. No sulfonamide was detected in the blood. A stool was watery brown and guaiac negative.

The serum was found to contain agglutinins for all Rh+ cells, and autoagglutination was observed with the patient's own cells and serum. Consequently all transfusions given were Rh- and there was no evidence of reaction to any of them.

During the first 6 days the patient was given considerable quantities of whole blood plasma isotonic saline solution and glucose intravenously, as well as penicillin for the pelvic infection and digitalis as prophylaxis against the development of heart failure and pulmonary edema. Within 48 hours she became more lucid, and she was rational after the 3rd day. The blood urea nitrogen continued to rise, however, and the urinary output averaged below 100 cc. daily through the 9th day. Nausea and vomiting persisted. With the development of edema and bilateral hydrothorax on the 6th day fluids were temporarily restricted.

On the 10th day diuresis began, with disappearance of the edema, slow decrease of the blood urea to normal and cessation of the nausea and vomiting. With the exception of an unexplained febrile period during the discontinuance of penicillin between the 23rd and 27th days recovery was uncomplicated. The patient was discharged in good health on the 69th hospital day. The results of renal function tests at the time of discharge and following discharge are presented in Figure 2.

The patient returned 1 month later for further studies. She had felt well in the interval. On the day prior to admission, however, slight right upper-quadrant pain, nausea and vomiting had developed. The sclerae were slightly icteric and the serum bilirubin was elevated.

Even before this admission, several cases of jaundice had been traced to a plasma pool from which this patient had received plasma 3 months previously and the development of hepatitis was anticipated. For 4 days the patient appeared to do well although the prothrombin time fell to 20 per cent of normal and the serum bilirubin climbed to 13 mg. per 100 cc. On the 5th day she rapidly lapsed into coma, dying 48 hours later of homologous serum hepatitis.

Autopsy Post mortem examination revealed the body of a normally developed and well nourished woman. The skin and sclerae were markedly icteric. The heart and lungs were not remarkable. The liver, which weighed 1050 gm., was the usual shape but flabby in consistency and the capsule was wrinkled; the organ was dull yellow brown. The cut surfaces varied in appearance. Large areas were uniformly pale yellow brown and the lobular markings were indistinct. Elsewhere the abscesses were accentuated and bright red, and the intervening parenchyma was pale yellow and apparently decreased in amount. There was no dilatation of the

*The details of this heterogeneous plasma pool have been reported elsewhere and the danger of transmission of homologous serum hepatitis by the use of pooled plasma emphasized.

*From the Department of Medicine and the Department of Pathology, Peter Bent Brigham Hospital, and the Department of Pathology Harvard Medical School.

§Instructor in medicine, Harvard Medical School; junior associate in medicine, Peter Bent Brigham Hospital.

bile passages, and examination of the gall bladder and extrahepatic bile ducts was negative

The spleen weighed 355 gm and was larger than normal, but was of the usual shape it was soft in consistence The

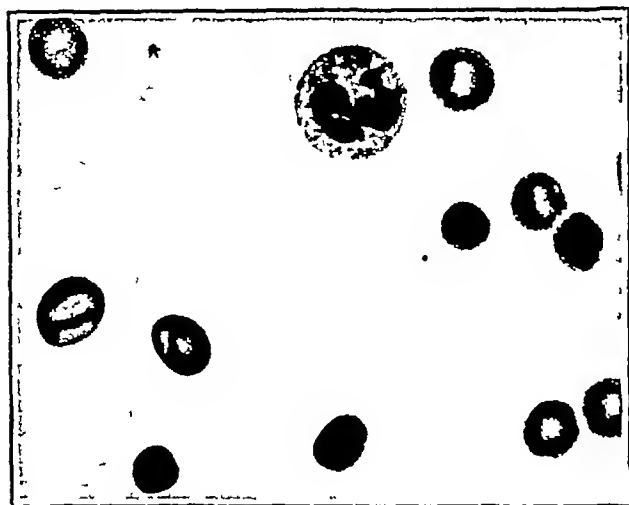

FIGURE 1 Smear of Patient's Blood on Admission (Wright's stain)

This shows several densely staining spherocytes

capsule was intact and free from adhesions Cross sections were red gray, and the malpighian corpuscles were prominent

The right kidney weighed 140, and the left 180 gm Both kidneys were similar and of normal shape and size They

The renal capsule was thin, gray and translucent and could be stripped from the kidney surface with ease. The capsular surfaces of the kidneys were pale brown and uniformly and firmly granular The cut surfaces were light brown, and the demarcation between the cortex and the medulla was sharp and distinct The width of the cortex

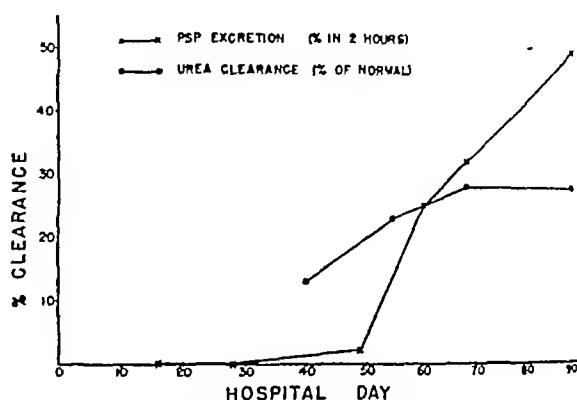

FIGURE 2 Renal-Function Tests

varied between 0.6 and 0.8 cm The cortical surfaces were mottled, and their markings were indistinct. The pyramids presented the usual appearance The calyces, pelves and ureters were not remarkable

Examination of the remaining organs revealed nothing of note

For microscopical study, blocks of kidney tissue were fixed in Zenker's acetic acid solution and 10 per cent formalin

FIGURE 3 Photomicrograph (low power) of the Kidney Cortex (phosphotungstic acid-hematoxylin stain)
Note the pattern of the scarring

were surrounded by a moderate amount of perirenal fat, which was not adherent to the capsule At the hilar region, the vessels and ureters were arranged in the usual manner

Sections were stained with eosin methylene blue, Mallory's phosphotungstic acid hematoxylin, Mallory's aniline blue and Turnbull's blue stain for iron

The changes observed on histologic examination were definite but not extensive. There was diffuse subcapsular scarring which frequently formed into narrow radial bands extending deep into the medulla. The fibrous tissue was occasionally pale and edematous. Throughout the scarred areas, particularly in the cortex, occasional small focal collections of lymphocytes were observed. Lymphocytes were also present in the pelvic fat and in the connective tissue beneath the pelvic epithelium (Fig. 3).

The greater number of the glomeruli were normal in appearance. The glomeruli in the scarred areas showed slight pericapsular scarring but were otherwise not remarkable.

Some of the convoluted and more particularly the collecting tubules especially those in the outer zone, were dilated and their lining epithelium was flattened. A few of these tubules contained pale, acidophilic-staining hyaline casts and, rarely, desquamated epithelial cells. The pattern of the involved tubules was such as to suggest the destruction of a nephron or a group of nephrons. By far the greater number of tubules showed no evidence of damage beyond slight cloudy swelling. Brown pigment granules that gave a positive reaction for iron were occasionally found in the tubular cells and throughout the stroma.

The blood vessels showed no visible involvement in either the scarred or the nonscarred areas.

Examination of sections of the liver showed massive destruction of the cells with consequent loss of architecture. The liver cells were shrunken with poorly stained cytoplasm and indistinct nuclear and cell outlines. There was marked polymorphonuclear infiltration about the portal areas and slight infiltration throughout the other areas. The bile ducts were intact for the most part, and in a few areas bile-duct proliferation was noted.

The sinuses of the spleen were engorged by red cells. A few macrophages contained hemosiderin. The malpighian corpuscles were enlarged but were made up of mature cells and they were infiltrated by a few polymorphonuclear cells. There was no increase in fibrous tissue.

Sections of femoral and rib bone marrow were examined. There was marked activity in both the red-cell and the white-cell series. No abnormal forms were noted. Megakaryocytes were numerous.

DISCUSSION

Nature of the Hemolytic Reaction

This patient developed a massive hemolytic reaction following an abortion. Although the anemia may have been due in part to bleeding, the dark urine containing blood pigments and the hemoglobinemia, abnormal fragility and spherocytosis of the red cells left no doubt that an acute hemolytic process was still in progress at the time of admission. Spherocytosis has been shown to be an indication of damage to the erythrocyte in various acute hemolytic anemias.² Abnormal agglutination and leukemoid white-cell reaction have also been observed in acute hemolytic anemia.³ All these abnormalities, with the exception of the anemia, disappeared a few days after admission. The diminution of spherocytosis and fragility closely paralleled one another.

The possibility of a hemolytic transfusion reaction in the first hospital seems to be excluded by the bronze skin on admission to that hospital, the hemolyzed blood drawn for the initial matching and the fact that when the donor and recipient bloods were rechecked, both were found to be Type A and Rh+. Repeated attempts to demonstrate any subgroup Rh agglutinins* in the recipient's blood were unsuccessful. These observations indicate that

the hemolytic reaction occurred before the patient received blood, presumably as a complication of the abortion.

Drugs capable of producing hemolysis that might have been employed include the sulfonamides, quinine and abortifacient pastes. No sulfonamide was found in the blood on admission. In view of the oliguria, which would have prevented appreciable excretion of sulfonamide and thus made detection possible, sulfonamide hemolysis was not likely.

The use of quinine as an oxytocic by illegal abortionists is an old practice, and it may have been used in this case. Cases of hemoglobinuria following

TABLE 1 Blood Data

TIME OF DETERMINATION	SPHEROCYTES per 100 red cells	SERUM HEMOGLOBIN mg/100 cc	SERUM BILIRUBIN mg/100 cc

After eight hours	8	222	1.48
After twenty hours	4	128	1.20
After eighty hours	2	54	0.90

quinine medication in patients without malaria have been reported.⁴⁻⁶ The cases reported by Wakeman et al.⁴ and by Terplan and Javert⁵ also occurred in pregnant women who had been given quinine as an oxytocic. The case of Wakeman and his associates was so similar to the one reported above that the following summary is presented.

A 20-year old woman took quinine and ergot to induce an abortion. Three days later she noticed severe lumbar pain and began to vomit. She became jaundiced. On admission to the hospital the urine was dark, bloody red. The serum was very dark. Attempts to group the patient's blood showed that the serum agglutinated the cells of all donors. Severe oliguria developed and the nonprotein nitrogen rose to 237. Hemoglobin which was 73 per cent on admission fell to 43 per cent. Diuresis began on the ninth day and the patient recovered. Re-examination of the blood later failed to show the pan agglutination observed initially.

Severe intravascular hemolysis following the use of abortifacient pastes introduced into the uterus has been described,⁷ the hemolysis being effected by the direct action of soft soaps on the red cells once they gain entrance to the blood stream.

Although the specific cause of hemolysis cannot be stated with certainty, the best explanation of the hemolytic reaction in this case seems to be either the introduction of an excess of a lytic substance into the blood stream by way of the uterus or sensitivity to orally ingested drugs.

Physiological Changes following Hemolysis

The clinical and hematologic data and fluid balance in the case reported above are presented in Table 2. The severe uremia at the onset was undoubtedly due in large part to the liberation of nitrogenous material from the metabolized red cells, as in other types of hemolytic anemia.⁸

*Rh+ are indebted to Dr. Louis K. Diamond for the Rh typing.

*Estimated.

Oliguria, amounting almost to anuria, extended over a period of twelve days, and persistent vomiting during that period not only made feeding by mouth impossible but also caused considerable loss of electrolytes. Therapy was aimed at replacement of water, salt, plasma protein and erythrocyte deficits. Glucose and plasma served to satisfy metabolic needs in part and to prevent excessive tissue catabolism. Greater restriction of fluid was necessary at the end of the first week with the

day. Pyuria also persisted until that time. The specific gravity was fixed during the first hospital admission at 1.010. On readmission a causal specimen showed a specific gravity of 1.018. These observations are all consistent with the pathological localization of the renal lesions primarily in the convoluted tubules, with subsequent repair.

It is interesting to observe that hematopoiesis was depressed during the period of convalescence so long as the blood urea nitrogen was elevated, and

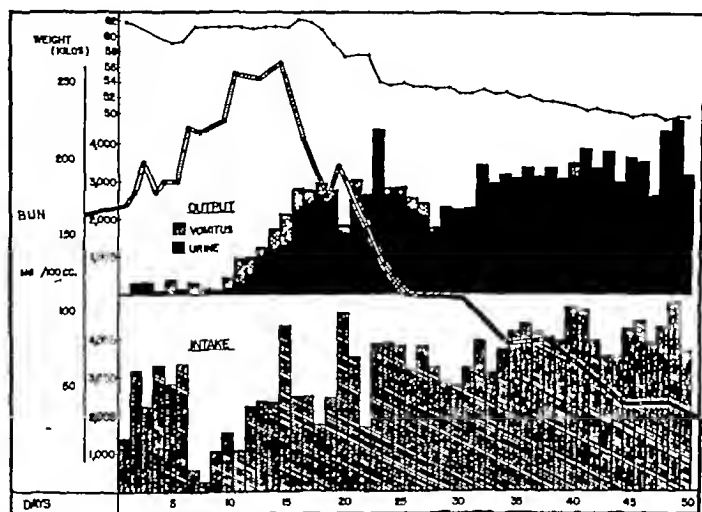

FIGURE 4 Chart Depicting the Fluid Balance of the Patient during the Period of Anuria and Recovery

development of edema and hydrothorax. No determinations of serum potassium were made, but electrocardiographic changes consistent with high potassium levels⁹ were not found.

With the onset of diuresis on the tenth day, the maintenance of fluid and electrolyte balance became easier. Renal function was so impaired at that time, however, that the blood urea nitrogen continued to rise (Fig 4). Urea clearance over the following weeks improved (Fig 2), and normal blood values were reached on the fifty-fourth day. Phenolsulfonphthalein excretion was likewise negligible at first. Inability of the tubular cells to reabsorb salt was demonstrated by a progressive fall in the blood chloride to 76 milliequiv per liter on the eighteenth day. Subsequently, it was necessary to provide from 3 to 12 gm of salt daily to keep the patient in salt balance. Proteinuria—as much as 8 gm was excreted on the fifteenth day—gradually diminished, disappearing on the forty-fifth

day. Pyuria also persisted until that time. This patient was studied by the injection of radioactive iron intravenously and showed, as all uremic patients do, a decreased utilization of iron for hemoglobin formation.¹⁰ When the azotemia had disappeared, however, active erythropoiesis was resumed, and a deficit of approximately 900 cc of red cells was made up in a little more than a month.

HEMOGLOBINURIC NEPHROSIS

Occurrence

The majority of reported cases of hemoglobinuric nephrosis have occurred after transfusion reactions due to incompatibility between major blood groups or to Rh incompatibility.

Hemoglobinuric nephrosis also follows blackwater fever,¹¹⁻¹³ favism,¹¹⁻¹⁷ hemolytic reactions due to sulfonamides,¹⁸⁻²⁰ plasmoquine²¹ and quinine²² intoxication, arsine poisoning²³ and hemolytic reac-

tions following burns²⁸ and the intravenous injection of distilled water²⁹

Hemoglobinuric nephrosis is rare or has not been reported in certain other hemolytic syndromes — namely, paroxysmal cold hemoglobinuria, paroxysmal nocturnal hemoglobinuria, cold hemoglobinuria due to a high titer of cold agglutinins and hemolysis of the recipient's cells due to a high titer of isoagglutinins in Group O blood from a universal donor

*Renal Pathology**

The pathological changes in the kidneys following intravascular hemolysis are described by a number of authors,³⁰⁻³² but the most complete description of the sequence of events is given by Ayer and Gauld.³³ These writers describe the autopsy findings in 7 patients who died three hours to ten days after hemolytic reaction

Three hours after hemolysis there was glomerular swelling, slight cloudy swelling of the proximal convoluted tubules and pale acidophilic material in the lumens of the proximal tubules, which became dark red to brown in the distal convoluted and collecting tubules. No interstitial edema or leukocytic infiltration was noted

By the third day there was considerable brick-red pigment within the cells of the distal convoluted tubules and some sloughing of these cells. The glomeruli and the proximal convoluted tubules were normal in appearance. By the sixth day there was considerable interstitial edema and leukocytic infiltration around the convoluted tubules. There was marked desquamation of the tubular cells, and some of the pigment of the lumens was turning greenish yellow. By the seventh day a few mitotic figures appeared in some of the tubular cells, indicating attempts at repair. Destruction of tubular cells and interstitial infiltration and edema were still more pronounced

By the tenth day there was complete destruction of some tubules, which were replaced by inflammatory cells and fibroblasts. There were numerous cellular casts in the distal convoluted and collecting tubules. Practically all the inflammation was around the distal convoluted tubules. There is little information available regarding what happens after the tenth day in cases that go on to recovery. Except for a case in which the patient recovered from a transfusion reaction and died fourteen months later of a pre-existing chronic glomerulonephritis, no autopsy reports of patients who had recovered from a hemoglobinuric nephrosis could be found

The changes found in the kidneys in the case presented above were consistent with the healed stage of the pathologic sequence described. The

pattern of scarring suggests that single nephrons or groups of nephrons had been destroyed. Added support to this thesis is the fact that few glomeruli and no blood vessels were involved, and none of the changes were those that are seen in the usual types of kidney disease

Pathological descriptions of the renal lesions in other varieties of hemoglobinuria^{6, 20, 34} are identical to those mentioned above after incompatible transfusion reactions

Pathogenesis

In early pathological studies, emphasis was placed on the capacity of heme pigments to block renal tubules. Animal observations showed a much greater tendency for hemoglobin precipitation in acid urine³⁵, accordingly, it was assumed that renal damage was directly related to hemoglobin precipitation, which in turn was related to urinary acidity

There are noticeable exceptions to this explanation.^{11, 33} Both experimentally and clinically, it has been noted that hemoglobinuria in the presence of an acid urine does not always result in oliguria and, conversely, that preliminary alkalization does not always protect against severe or fatal renal damage. Fatal cases have been reported in which there has been too little renal precipitation of hemoglobin in the pathological sections³⁶ to account for anuria. Foy et al.,¹¹ in an excellent review on this subject, concluded that precipitation of hemoglobin is secondary to the oliguria and not the cause of it

Apparently, a number of factors may operate to produce renal damage, and prominent among these is shock, regardless of the cause. Whether from hemolytic anemia, toxins, infections or trauma, the renal changes are strikingly similar.³⁷ The resulting tubular necrosis is considered to be due to anoxia from the critically reduced renal blood flow. The presence of hemolysis has been shown to cause further reduction of renal blood flow through local vascular spasm.³⁸ Finally, Yuile³⁹ has demonstrated quite clearly that tubular necrosis due to anoxia results in extensive hemoglobin precipitation in the tubules of experimental animals

Dehydration and electrolyte imbalance contribute to circulatory failure. Vomiting may be severe with the sudden azotemia and, in the absence of renal regulation, may increase electrolyte loss, which in itself can perpetuate renal dysfunction.¹¹

The careful observations of Bing⁴⁰ indicate a difference in toxicity of certain products of hemoglobin. Methemoglobin appeared much more toxic in acidotic dogs than bivalent hemoglobin. Formation of methemoglobin in blood serum is dependent on the length of time the hemoglobin is circulating in the serum and on the reducing capacity of the serum, in the urine, methemoglobin formation is greater in acid mediums. The possibility that other hemoglobin derivatives such as hematin cause local renal injury is suggested

*After this article was submitted an excellent study of the pathology of hemoglobinuric nephrosis and related conditions was published by Lucké (Lucké B. Lower nephron nephrosis: renal lesions of crush syndrome, of burns, transfusions and other conditions affecting lower segments of nephrons. *Mil Surgeon* 99:371-396, 1946)

As Foy et al¹¹ point out, most of the experimental studies on hemoglobinuric nephrosis have been carried out with the observer's attention concentrated on one factor. It seems fairly evident that no one factor is solely responsible for the renal change, and further studies in which each of the various factors is carefully controlled are necessary for a complete understanding of the pathogenesis.

Prognosis

The mortality rate for hemoglobinuric nephrosis cannot be accurately calculated from the published

the case reported above are shown in Figure 2. The rate of recovery was slow, but the degree of recovery was fairly complete. The final phenolsulfonephthalein determination was probably deceptively high, owing to the impairment of liver function existing at the time, but the curve shows progressive improvement until the time of death. The urea clearance apparently remained stationary at about 30 per cent between the seventh and nineteenth days.

The prognosis of this renal lesion has much in common with other types of tubular damage, such

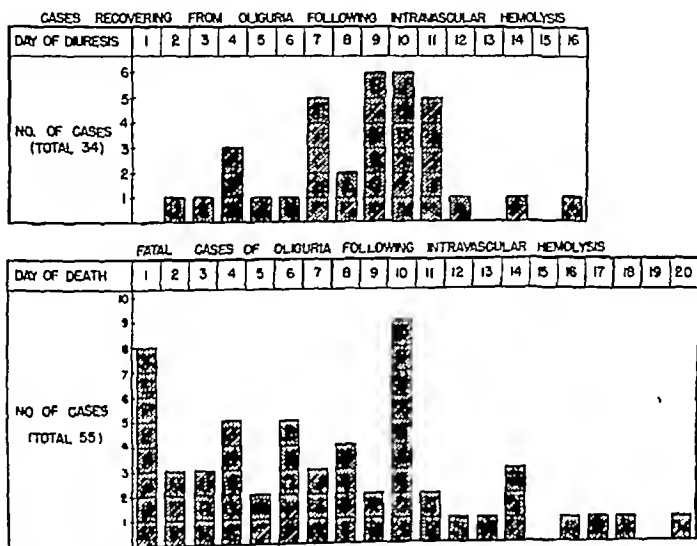

FIGURE 5 Day of Diuresis or Day of Death in the Cases of Oliguria following Intravascular Hemolysis Reviewed in the Literature

cases, since a greater proportion of fatal than nonfatal cases have undoubtedly been reported. Fifty-five fatal and 34 nonfatal cases of hemoglobinuric nephrosis collected from the literature are presented in Figure 5 according to date of death or onset of diuresis. It is apparent that the critical period following the hemolytic reaction lasts approximately two weeks. If the patient can be kept alive through that period, the kidneys may be expected to resume adequate function.

In only 7 of the 34 nonfatal cases were renal-function tests performed after clinical recovery. In all these cases function was normal, or nearly so. No case was encountered in the literature in which renal damage due to hemoglobinuria persisted for as long as a year. The results of the renal-function tests in

as bichloride of mercury poisoning and shock states. Except for the initial accelerated rise of the non-protein nitrogen with blood destruction, each case goes through the same critical period, repair proceeds at the same rate, and functional recovery is practically complete.

Therapy

Treatment may be divided into the periods of hemoglobinemia, anuria and diuresis.

In the acute reaction with hemoglobinuria immediate attention should be directed to the prevention of shock and the promotion of renal blood flow. Transfusion is indicated, particularly in the presence of anemia. Plasma in amounts up to 1 or 2 liters a day or even physiologic saline and

glucose solutions are useful. Amounts of crystalloids in excess of 2 or 3 liters a day, however, are to be guarded against, because of the danger of edema if anuria develops. Immediate alkalization is indicated in spite of the conflicting experimental evidence regarding its effects. This may be done by the injection of 6 gm of sodium citrate, lactate or bicarbonate intravenously over a period of five or ten minutes.⁴¹ The large doses of potassium sometimes advocated for alkalization are not without danger,⁹ particularly in view of the large amount of potassium already liberated by the hemolytic reaction.

After the first one to four days, the hemoglobinemia will have disappeared, and renal shutdown taken place. As indicated above, the lesion is reversible, given sufficient time for repair. The important factor, therefore, once anuria has set in, is time, and the maintenance of the patient depends on the prevention of edema and congestive failure, maintenance of blood volume and renal blood flow, maintenance of electrolyte balance and provision of basal nutrition requirements.

The anuric patient differs from other patients in an important respect: water and not salt is the important factor in edema formation. Without renal excretion there is a relatively fixed daily fluid output through other channels. If the fluid intake exceeds this, edema follows, regardless of the electrolyte situation. Fluid retention, in addition to causing congestive heart failure, produces functional impairment of other vital organs, particularly the brain, with cerebral edema, convulsions, coma and death. With its volume limited by a fibrous capsule, the kidney parenchyma is likewise affected by edema.

Fluids should be limited to about 1500 cc a day, subject to modification according to the cardiac reserve and evidence of congestive failure. Blood and plasma are useful in maintaining the blood volume. Electrolyte supplements are necessary to replace those lost from the body by vomiting and diarrhea. These are prescribed according to daily determinations of the total protein, chloride and carbon dioxide combining power. Prophylactic digitalization is indicated to prevent congestive failure. Should cardiac function be impaired at the onset, it may be anticipated that the patient will not survive the critical period of one or two weeks. Under such circumstances, peritoneal irrigation may be life saving. It has been demonstrated that the peritoneal surface serves as an adequate excretory organ (by diffusion) if irrigated with the proper solution.⁴² Renal decapsulation has been reported to produce dramatic results in a few cases, and it affords an opportunity for renal biopsy. It is directed, however, at prevention of the harmful effects of renal edema, which may at least in part be controlled by limited fluid administration.

Although the urine volume may become greater than normal shortly after the onset of diuresis, the nonprotein nitrogen may continue to rise. The urine at that time is almost a pure plasma filtrate—instead of the glomeruli putting out 170 liters of fluid a day and the tubules absorbing 99 per cent of the fluid, the kidney excretes 2 or 3 liters of what is approximately plasma, partially filtered of protein. This lack of tubular activity is shown as the diuresis progresses, by an inordinate loss of sodium chloride, which in itself may cause severe renal dysfunction unless corrected.⁴³ It is conceivable that other elements usually reabsorbed escape into the urine in excess—that is, glucose, calcium and potassium—and in themselves cause deficiency syndromes.

The period of tubular repair following the onset of diuresis may last from several weeks to several months. During this period of repair, fluids should be forced, and the intake of salt kept high (between 6 and 12 gm daily) to compensate for the salt-losing tendency that persists until the tubular damage is repaired.

SUMMARY

The pathogenesis of hemoglobinuric nephrosis is discussed, and suggestions regarding therapy are made.

A case of hemoglobinuric nephrosis following massive intravascular hemolysis is presented. The patient recovered but died three months later of an acute hepatic necrosis due to homologous serum hepatitis.

Renal-function tests improved until the time of death, indicating eventual complete recovery, and autopsy showed little residual kidney damage.

GRANULOMA INGUINALE WITH PERIANAL INVOLVEMENT

Report of a Case

JOSEPH BERKOWITZ, M.D.*

BOSTON

GRANULOMA inguinale is an unusual skin disease found preponderantly in Negroes. The lesion begins as an ulceration in the groin or about the genitals and over a period of years, if untreated, spreads locally and progresses to a chronic inflammatory granulomatous stage. A gram-negative encapsulated bacillus appearing as a rod-like structure (Donovan body) in large mononuclear cells is the etiologic organism.^{1,2}

Involvement about the anus is rare, and yet within the past year 2 cases with perianal disease have been described in Negro soldiers stationed at a camp in Massachusetts.³ In the ulcerative stage the chief complaints are pain and perianal drainage. The pain is constant and annoying on sitting and on walking but is agonizing on defecation, especially if the anal canal is involved. Drainage is bloody, serous or purulent, resulting in redness and irritation of the perianal skin. With progress of the disease and granuloma formation the pain tends to diminish in intensity, and the drainage becomes more profuse and foul smelling. Specific treatment consists of two courses of intramuscular antimony (Fusidin).

Inasmuch as granuloma inguinale is found primarily in warm climates and particularly in Negroes, the following case in a white man is considered worthy of report.

A 29-year-old man was seen in consultation on July 5, 1946, because of a painful draining perianal mass of 9 months duration. He had been born in the northeast section of Massachusetts and except for a short period in the military service, had spent his entire life there. While in the service he had been stationed at various camps in Massachusetts, Florida and Texas. In August, 1945, he had been separated from the service because of poor vision. In September he had first noticed a small tender swelling just to the left of the anus associated with severe pain on defecation. The bowel movements at that time were scybalous and there was occasional bright-red staining on the toilet tissue. A physician informed him that he had a "pimple" 1 cm from the anus and prescribed a dark salve for local application and also warm water poultices. Within a few days the mass broke down, and purulent drainage ensued. During the next few months there was intermittent crusting and recurrent drainage. The pain became intolerable and was controlled by narcotics. In April, 1946, the patient was seen by another physician who advised admission for observation to a hospital where physical examination disclosed a well developed and well nourished man who stood with the feet apart and who was bent forward for relief of pain. The right side of the anal canal contained a large area of ulceration extending down to the scrotum that bled easily after the overlying purulent discharge and debris had been removed and on which pink granulations were noted. On the left side a smaller area about 5 cm in diameter, was noted. The sphincter was intact and painful to examination. There was

*Assistant in proctology. Beth Israel Hospital; assistant in proctology, Boston Dispensary; proctologist, Phelan Hospital, Brockton.

no evidence of hemorrhoids or fistulas. On April 29 the pathological report on a biopsy specimen taken 2 days previously revealed marked chronic inflammation and epithelial hyperplasia, early carcinoma could not be ruled out. On May 10 section of the left inguinal lymph node showed essentially normal lymphoid tissue, and the capsule disclosed slight round-cell infiltration. On May 25 biopsy of the rectum revealed marked acute and chronic inflammation compatible with lymphogranuloma inguinale. A Frei test was suggested. On May 28 it was stated that the picture was one of chronic and acute inflammation, of nonspecific type, there was no evidence of cancer. After 41 days of hospitalization, the treatment consisting of wet dressings and 6,360,000 units of penicillin, the patient was discharged unimproved, in agonizing pain — especially on defecation — and draining a profuse amount of foul pus from the perianal lesion.

The past history was entirely negative for serious sickness or operations. There was no history of contact with Negroes or of any unprotected contact.

Physical examination disclosed a young man lacking in education and of low intelligence who was poorly nourished and in obvious acute distress. Except for the perianal region,

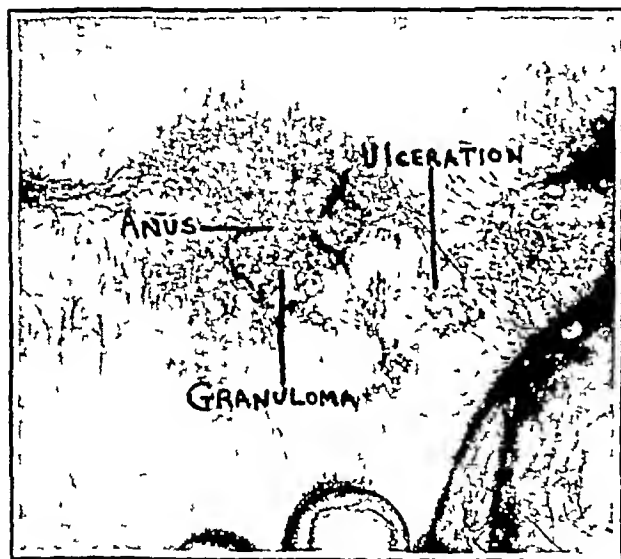

FIGURE 1 Photograph of the Active Lesion

The lesion on the anterior and left lateral aspects of the anus is ulcerated, granulomatous and covered with pink, easily bleeding granulations.

the skin was clear. The pupils reacted equally to light and to accommodation. There was no adenopathy. The heart sounds were of good quality, with normal rate and rhythm. The chest expanded symmetrically, numerous crackling rales were heard over both bases, clearing after cough. Abdominal examination was negative. There was a healed scar over the left inguinal region. The genitalia were normal. The reflexes were equal and active. About the anus anteriorly and especially on the left side there was an elliptical lesion approximately 7 cm in length and 1 cm in width, ulcerated anteriorly and granulomatous along the left side (Fig. 1). The mass was covered with pink granulations, which bled easily on trauma. The slightest pressure resulted in such excruciating pain that further examination was deferred. A diagnosis of probable granuloma inguinale was made, and hospitalization arranged for the following day.

The temperature was 98.6°F, the pulse 96, and the respirations 20.

Examination of the blood revealed a red-cell count of 4,910,000, with a hemoglobin of 96 per cent, and a white-cell count of 12,600, with 57 per cent neutrophils, 18 per cent band cells, 19 per cent lymphocytes and 6 per cent monocytes. The bleeding time was 3 minutes (Duke), and the clotting

time 5 minutes (capillary tube), and the sedimentation rate 10 mm in 1 hour (Wintrobe method). The Frei test and the blood Hinton test were negative 72 hours after admission. The urine was straw colored, cloudy, and alkaline, with a specific gravity of 1.016, tests for albumin and sugar were

negative. Microscopical examination of the sediment was negative for red cells and casts.

Strict bed rest was enforced and Furacin ointment dressings applied to the perianal region, 0.06 gm of codeine sulfate

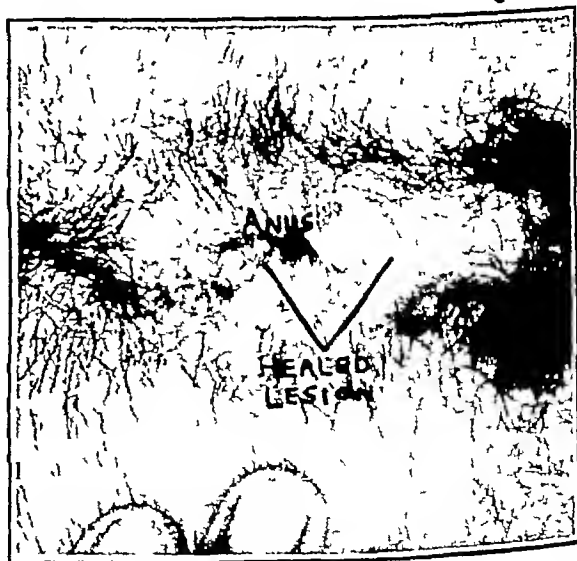

FIGURE 3 Photograph of the Healed Lesion

The perianal lesion is healed after fourteen days of specific treatment.

and 0.6 gm of aspirin were administered for relief of the pain. Intragluteal injections of Fuadin (sodium antimony-III biscatechol disulfonate of sodium) were instituted on the day of admission, alternating buttocks being used, and a complete course (40 cc) given according to the following schedule on

July 6, 7, 8 and 10 respectively, 1.5, 3.0, 5.0 and 5.0 cc., followed by 5.0 cc. every other day until the full amount had been given. Biopsy specimens and smears were taken from the perianal lesion on July 9. The smear was negative for acid fast bacilli and for inclusion bodies. Microscopical examination of one biopsy specimen revealed a thickening of the epidermis, with edema, polymorphonuclear-cell and lymphoid cell infiltration of the papillae and a dense lymphoid and plasma-cell exudate in the subepithelial connective tissue. There was no evidence of tuberculosis, and the inflammatory process was considered nonspecific. The diagnosis was chronic and acute inflammation. Microscopical examination of the other specimen disclosed marked chronic inflammation and epithelial hyperplasia compatible with granuloma inguinale (Fig. 2).

On the 4th hospital day there was little drainage and the pain had diminished noticeably. At that time the ulcerated portion of the lesion showed evidence of crusting and drying and there was a definite decrease in redness about the entire area. Clinical improvement was marked and the patient was allowed out of bed. During the following week the ulceration gradually healed, and the granuloma was absorbed. All symptoms subsided. The first course of treatment was completed on July 20, and 2 days later the patient was discharged to his own physician for the second course, with the lesion apparently healed (Fig. 3). Despite the fact that this course was never completed, owing to indifference on the part of the patient, there has as yet been no recurrence.

Several aspects of this case are worthy of consideration. The diagnosis of granuloma inguinale is extremely difficult, not only because the lesion is not suspected but also because smears and biopsy

specimens often do not reveal the diagnostic bacteriologic and pathological findings. The disease should be suspected in every ulceration or granuloma of the anogenital region that is resistant to antibiotics and to chemotherapy. Even though the characteristic macrophage with intracellular Donovan bodies is not found on smear examination and the pathological picture is that of acute or chronic inflammation or of nonspecific granuloma, a therapeutic trial of intramuscular antimony (Fuadin) should be instituted.

Granuloma inguinale can become a chronic disabling disease, if not recognized. Clinical response to Fuadin is usually prompt, dramatic and specific. The case reported is of interest in that it occurred about the anus and in a white man living in Massachusetts.

MEDICAL PROGRESS

"FOLIC ACID" PTEROYLGLUTAMIC ACID AND RELATED SUBSTANCES*

FREDERICK SARGENT, II, MD†

CHICAGO

DISCOVERY, SYNTHESIS AND CHEMISTRY

THE discovery, isolation, synthesis and clinical use of a new member of the vitamin B complex called "pteroylglutamic acid" can be attributed to the combined efforts of many different investigative groups. During the past sixteen years this substance has ascended from bacteria to chick, from chick to rat, from rat to monkey and from monkey to man as an essential nutrient. During its ascent, but before its isolation and synthesis, this substance picked up many names (Table I), for each group of investigators that studied it did not then realize that their material was quite similar to that described by others. This varied nomenclature was the natural consequence of preliminary work on an unknown substance, but the identity of this nutritive essential was clarified when it was shown that the factor in liver essential for the growth of *Lactobacillus casei* was also necessary for chicks, rats, monkeys and man.

Various investigative groups have demonstrated that in such foods as yeast, liver and spinach, there is a substance or group of substances that is closely associated with known members of the vitamin B complex and is necessary for the growth and hematopoiesis in the chick, the rat and the monkey, as well as for the growth of certain bacteria. Investigators working chiefly with yeast isolated a material known as the *L. casei* factor because it was necessary for the growth of that organism.²⁻⁴ From liver a substance was isolated that prevented the development of anemia, leukopenia and thrombocytopenia and restored growth in the chick.¹⁻⁴ This substance was called vitamin B₁₂. From both liver and yeast a factor was isolated that prevented the development of cytopenia and a sprue-like syndrome in monkeys fed a synthetic diet containing all previously known essential nutrients.²⁻⁴ This factor was named vitamin M. As knowledge of these apparently different factors accumulated, it occurred

*Based on a talk presented at a meeting of the Began Society of Boston University School of Medicine, Boston, on April 7, 1947.

†Formerly fourth-year student, Boston University School of Medicine.

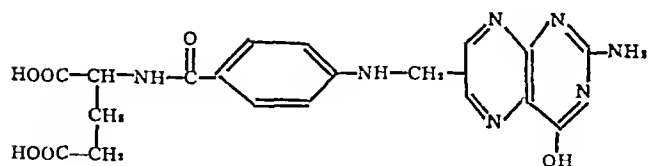

to various investigators that they might be dealing with the same substance. It was rapidly shown that the *L. casei* factor could replace vitamin B₁₂ in chick nutrition and could correct the sprue-like syndrome in monkeys deficient in vitamin M²⁻⁴. Furthermore, it was found that the *L. casei* factor corrected the anemia, leukopenia and granulocytopenia and restored growth to rats fed sulfonamides²⁻⁵. When it had been demonstrated that these various factors

Monkey	Vitamin M
Man	Wills factor (?)

*Folic acid was the name given by Mitchell and his associates¹ to a factor extracted from spinach, essential for the growth of *S. lactis R*. This substance is not identical with the *L. casei* factor but has been extracted from liver, kidney, yeast and mushrooms. "Folic acid" has come into popular usage as the descriptive term for pteroylglutamic acid and its related substances. Throughout this paper these substances are designated by their accepted chemical names when the names are known.

were probably closely related, if not identical, the *L. casei* factor was crystallized from a liver concentrate, its chemical structure determined, and its synthesis achieved^{2-4, 6}. The active nutrient thus isolated proved to be a relatively simple organic compound containing the amino acid, glutamic acid, para-aminobenzoic acid and the pterin nucleus related to xanthopterin, the chemical that gives the yellow color to the butterfly wings. These various fractions of the active material are combined as follows:

This compound is called pteroylglutamic acid. It is the active substance in the preparations formerly called vitamin B₁₂, vitamin M and *L. casei* factor. "Folic acid" is the term that, by popular usage, has become synonymous with pteroylglutamic acid, but throughout this review the latter chemical name is used. Pteroylglutamic acid is a bright-yellow material that is only slightly soluble in water. Its sodium salt is more soluble. Sunlight has a destructive action on a solution of pteroylglutamic acid, and this compound is rapidly destroyed by heating with dilute mineral acids.⁷

A series of compounds containing more than one glutamic acid molecule has been isolated from various sources. The active material in the preparation containing the so-called "fermentation *L. casei* factor" has recently been identified and synthesized. This factor occurs in a concentrate of the filtrate obtained from the products of aerobic fermentation of an unidentified bacterium of the genus *Corynebacterium*.⁸ The active material possesses two extra glutamic acid molecules bound through a peptide linkage to pteroylglutamic acid. This compound is known as pteroyltriglutamic acid (or pteroyl diglutamyl-glutamic acid). A different chemical was isolated from a yeast concentrate. This compound, formerly known as vitamin B₁₂ conjugate, proved to have six molecules of glutamic acid combined—probably through a peptide linkage—to pteroylglutamic acid. Hence, it was named pteroylheptaglutamic acid (or pteroyl-hexaglutamyl-glutamic acid). The exact structure of this compound is not known, for it has not been synthesized. In the literature pteroylheptaglutamic acid is frequently referred to as "folic acid conjugate." Recently, a compound containing thirteen glutamic acid molecules has been isolated from yeast.⁹ The exact chemical structure has not been determined. On the basis of these chemical studies it seems reasonable to infer, as Thomson⁹ has implied, that a whole series of compounds that might collectively be called the pteroylpolyglutamic acids exists in nature.

Pteric acid is a synthetic compound containing no glutamic acid molecules.⁶ This compound has relatively limited biologic activity.

ASSAY AND NATURAL DISTRIBUTION

The amount of pteroylglutamic acid or its related conjugates in foods and biologic fluids can now be determined only by bioassay, the growth of *L. casei* or *S. lactis R* being used as the test organisms. The amount of growth of these bacteria in a given time is estimated turbidimetrically. From a standard curve the concentration of active material in the unknown substance can be estimated. This assay, to be accurate, depends on knowledge of the nutritional requirements of these test organisms. Table 2 presents the relative biologic activity of pteroylglutamic acid and related substances for *S. lactis R* and *L. casei*. Two points should be emphasized: the nutritional requirements of the test bacteria are different regarding their need for these growth-promoting factors and compounds containing more than one glutamic acid molecule are less active than pteroylglutamic acid in promoting growth.

It is the second point that is especially important in the assay of pteroylglutamic acid in foods, for in nature this nutrient almost uniformly occurs as pteroylheptaglutamic acid.¹⁰ Because this heptapeptide is relatively impotent as a growth-promoting factor, the compound must be hydrolyzed into simple

pteroylglutamic acid, which is a potent growth factor. This hydrolysis may be achieved in a number of ways. Some investigators employ the enzyme takadiastase, other workers use an alkaline or acid hydrolysis. In animal tissues an enzyme has been found that hydrolyzes pteroylheptaglutamic acid into pteroylglutamic acid and six molecules of glutamic acid.^{11, 12} This enzyme is designated vitamin B₉ conjugase because it splits the heptapeptide vitamin B₉ conjugate (pteroylheptaglutamic acid). Vitamin B₉ conjugase has been found in relatively abundant amounts in the liver, kidneys, bone marrow and pancreas. In the microbiologic assay for pteroylglutamic acid a water extract of fresh hog kidney is used as a source of vitamin B₉ conjugase.¹⁰ There is, however, a limitation to this method — namely, the occurrence in food of a substance called "conjugase inhibitor."¹⁰ Because this factor, which inhibits the activity of vitamin B₉ conjugase, occurs in variable amounts in food and because there is at

studied. Furthermore, the optimal daily allowance of this nutrient for human beings has not been determined.

PHYSIOLOGY

The reported signs of pteroylglutamic acid deficiency are summarized in Table 4. It is apparent that a wide variety of signs are associated with a

TABLE 3 Content of Pteroylglutamic Acid in Various Foods^{10, 13}

Food	PTEROYLGLUTAMIC ACID CONTENT microgram./100 gm.
Fresh deep green leafy vegetables	80-190
Liver	48-105
Fresh green vegetables; cauliflower	40-62
Kidney	35-47
Dry breakfast cereal prepared from wheat	19-46
Beef; veal	11-22
Root vegetables, tomatoes, cucumbers, light green leafy vegetables, bananas, pork, ham, lamb, cheese, milk, dry breakfast cereal prepared from rice or corn and many canned foods	0-20

TABLE 2 Relative Biologic Activity of Pteroylglutamic Acid and Related Substances¹

SUBSTANCE	ACTIVITY		
	S. lactis	R.	L. casei
Pteric acid	50.0	0.01

Pteroyllysylglutamic acid	0.5	0.2	

deficiency of this substance. Of special interest, however, are the hematopoietic disturbances in various animals and the syndrome similar to cytopenia and sprue that occurs in monkeys. The hematopoietic disturbances — anemia, leukopenia, granulocytopenia and thrombocytopenia — that occur in the lower animals do so in animals maintained on a synthetic diet containing all the known nu-

present no way of destroying it, assays employing vitamin B₉ conjugase are necessarily of limited value. By the use of amounts of conjugase in excess of the inhibitor content of the particular preparation being assayed, this difficulty may in part be overcome. No matter which hydrolytic method is employed, however, the amount of pteroylglutamic acid found in various foods varies rather widely, and to date a completely satisfactory method of assay has not been worked out.

With these limitations in mind, some of the recent work on the concentration of pteroylglutamic acid in foods is presented in Table 3. A number of points should be emphasized. In the first place, even in foods containing relatively rich quantities of pteroylglutamic acid, the amount available is low. In the second place, cooking and storage at room temperature effect large losses of this nutrient.^{10, 13} Finally, only small amounts of pteroylglutamic acid are present in the usual diet — amounts considerably less than that found therapeutically effective. The intestinal bacterial flora may contribute a large amount of this vitamin, for Williams and his associates¹⁴ have shown that a wide variety of bacteria can synthesize folic acid and that the rat may obtain as much as 70 per cent of the daily intake of folic acid from bacterial activity. Biosynthesis of pteroylglutamic acid in human beings has not been

TABLE 4 Reported Signs of Pteroylglutamic Acid Deficiency*

DEFICIENCY SIGN	TEST SUBJECT
Failure of growth	Chick, rat, guinea pig, mouse and monkey
Anemia	Chick, rat, monkey and man
Leukopenia	Rat, chick, monkey and man

Certain dermatologic syndromes	Man
Perosis	Chick

*Based on material presented by Daft.¹

trients except pteroylglutamic acid. This factor specifically corrects all these disturbances when added to the purified diet.¹⁵

In the syndrome similar to cytopenia and sprue that develops when monkeys are maintained on a purified diet, interest is great because of the homologous conditions in man — tropical and nontropical sprue and celiac disease. In fact, Jones, Warden and Darby¹⁶ suggest that lack of vitamin M in the monkey is the experimental analogue of sprue in man. This deficiency syndrome in the monkey

consists of anemia, leukopenia, thrombocytopenia, gingivitis, necrosis of the gums, anorexia, diarrhea, susceptibility to dysentery (experimental or spontaneous infection) and finally death^{17, 18} This syndrome, as well as sprue in man, responds to therapy with both pteroylglutamic acid and pteroyltriglutamic acid In addition to the steatorrheic diarrhea of man, certain cases of long-standing diarrhea among human beings have responded to treatment with pteroylglutamic acid¹⁹ Coca²⁰ reported that 6 patients with the dermatologic syndrome, who presented symptoms and signs that did not respond to routine therapy for allergy, were successfully treated with pteroylglutamic acid These patients had nervous symptoms or dermatologic disturbances, or both The former included "anorexia, weakness, uncontrollable nervousness and insomnia," and the latter either "chronic early inflammatory eruptions of both legs" or "widespread weeping eruption of limbs, body and face"

Because there is little fundamental knowledge concerning the mode of action of pteroylglutamic acid, few broad hypotheses have been suggested Two theories should be mentioned On the one hand it has been suggested that pteroylglutamic acid acts as a co-enzyme in the synthesis of thymine (5-methyl uracil—a pyrimidine not to be confused with thiamine) or a related compound¹⁵ The evidence for this mode of action, however, is far from convincing By analogy, it is reasonable to suspect a similar action with all the other known members of the vitamin B complex, which have been shown to act as co-enzymes in bodily metabolic processes Spies and his associates²¹⁻²³ have shown, in a small series of cases, that 5-methyl uracil in large amounts can be substituted for pteroylglutamic acid in the treatment of macrocytic anemias Petering and Delor²⁴ have demonstrated that 5-methyl uracil will not restore growth or correct the hematologic disturbances in rats deficient in pteroylglutamic acid The explanation may be that a large number of natural and synthetic hematopoietically active substances exist Such substances may be related chemically, and their mode of action may be similar³ On the other hand, it has been suggested that pteroylglutamic acid plays a role in nitrogen metabolism, for in rats casein affects a partial protective action against the production, by various sulfonamides, of signs of nutritional deficiency^{5, 15}

These hypotheses leave much room for fundamental research, but there is more knowledge regarding the action of these hematopoietic substances in Addisonian pernicious anemia In studying this disease investigators have employed two methods of assessing the activity of pteroylglutamic acid and its related substances the hematologic response, including cytologic changes in the bone marrow, and the urinary excretion of pteroylglu-

tamic acid following oral or parenteral administration of this substance or its relatives

In patients with pernicious anemia in relapse a satisfactory remission can usually be produced with pteroylglutamic acid The hematopoietic response to the heptapeptide, pteroylheptaglutamic acid, depends on the amount of conjugase inhibitor in the preparation If the inhibitor content is high, there will be no change in the blood picture If, on the other hand, the inhibitor content is low, there may be a hematologic remission²⁵ These data suggest that the patient with pernicious anemia cannot utilize the heptapeptide owing to an inability to neutralize the activity of conjugase inhibitor In cases undergoing remission, there is a reticulocytosis followed by a gradual increase in the red-cell count and hemoglobin, together with a conversion of the characteristic maturation arrest of bone marrow into a normal cytologic picture^{2, 3, 11, 12, 25-31}

What changes occur in urinary excretion of pteroylglutamic acid? Studies of this problem by Bethell and his associates^{25, 32} are the most complete to date The investigators divided the subjects into three groups normal subjects, patients with pernicious anemia in relapse and patients with pernicious anemia in remission on liver Each of these groups was studied while the subjects were on a standard low-protein, meat-free diet of adequate caloric value, while the standard diet was supplemented with pteroylglutamic acid and while the standard diet was supplemented with yeast containing an equivalent amount of pteroylheptaglutamic acid In the last, a variety of preparations containing different amounts of conjugase inhibitor were tested In no case was any heptapeptide found in the urine Three significant observations were made In the first place the normal person excretes equal amounts of pteroylglutamic acid whether the diet is supplemented with pteroylglutamic acid or purified heptapeptide When, however, a preparation of heptapeptide containing a large amount of inhibitor is used as the supplement, the excretion of pteroylglutamic acid is reduced Secondly, the patient with pernicious anemia in relapse excretes much less pteroylglutamic acid than the normal subject when the diet is supplemented with either pteroylglutamic acid or purified heptapeptide If such a patient is given a heptapeptide preparation that is rich in inhibitor, there is practically no increase in the urinary excretion of pteroylglutamic acid over that occurring while he is on the standard diet When given liver extract along with heptapeptide high in conjugase inhibitor, the patient with pernicious anemia in relapse will show no increase in urinary excretion of pteroylglutamic acid Finally, the patient with pernicious anemia in remission on liver excretes about the same amount of pteroylglutamic acid while receiving this supplement as the normal subject does When given the heptapeptide in addition to conjugase inhibitor, he is able

to excrete much more pteroylglutamic acid than the patient in relapse

Thus, the combination of liver extract and heptapeptide given to the patient with pernicious anemia in relapse does not cause an increased urinary excretion of pteroylglutamic acid. In a few patients with pernicious anemia in relapse receiving no supplement of heptapeptide, parenteral liver extract alone seems to cause a small but definite increase in the urinary excretion of pteroylglutamic acid.¹² This report has not yet been confirmed.

How are these preliminary metabolic studies to be interpreted? It appears that patients with pernicious anemia in relapse are unable to utilize pteroylglutamic acid because they are unable to neutralize the inhibitor. In contrast, patients in remission show marked improvement in their handling of heptapeptide. These observations are of interest, for studies in vitro have shown that the conjugase activity in tissues from patients with pernicious anemia is not significantly different from that of normal subjects.^{11, 12} On the basis of the evidence so far available two interpretations have been offered. It has been suggested, on the one hand, that purified liver extracts contain substances that correct some abnormality in the conjugase enzyme system in patients with macrocytic anemias. The mechanism may be the removal of an inhibitor substance of conjugase or the providing of substances necessary for proper functioning of this enzyme system. Secondly, the metabolic derangement may be more deeply seated than mere inability to utilize the heptapeptide of pteroylglutamic acid.¹¹ Of great interest in connection with the interrelations between pteroylglutamic acid and liver extract is the recent experiment of Elvehjem and his co-workers,¹³ who found that niacin-deficient dogs developed an anemia that ultimately failed to respond to niacin. No response to folic acid was noted, and refined liver extracts were effective only when the diets were high in casein or when supplements of pteroylglutamic acid were given. This point is more fully explained below.

PHARMACOLOGY AND TOXICOLOGY

Both in animals and in man pteroylglutamic acid and its relatives are nontoxic.¹⁴ In animals these substances are not irritating when injected subcutaneously. They do not affect the blood sugar, and there is only a weak action on the isolated intestine. Respiration is not influenced, and the effects on the blood pressure are minor. In long-term experiments, the daily intraperitoneal administration of 5 mg per kilogram of body weight for two months produced no unfavorable reactions in rabbits and rats. In a similar period, daily peritoneal injections of 50 mg per kilogram of body weight to rabbits and 75 mg per kilogram of body weight to rats caused minor changes in the kidney tubules but no deaths. The acute toxicity for ex-

perimental animals is low. The LD₅₀* for mice is 600, for rats, 500, for rabbits, 410 and for guinea pigs, 120 mg per kilogram of body weight.

In human subjects oral or intramuscular administration is essentially without toxic effects. Up to 150 mg has been given intramuscularly, and 500 mg orally in a single dose. Intravenous medication, on the other hand, is not recommended, for in a few cases rapid intravenous administration of 150 mg of pteroylglutamic acid has resulted in a shock-like reaction. The pulse has disappeared, the blood pressure has fallen, and unconsciousness has ensued. Fortunately, recovery has always followed within several minutes, although headache and nausea have persisted for as long as twenty-four hours. This shock-like reaction may, however, be due to impurities in the synthetic preparations.¹¹

The therapeutic dosage currently recommended by most authors is 10 mg daily by mouth.^{27, 27, 28} For maintenance, 5 to 10 mg usually suffices. In any case these doses may be varied depending on the individual case. Davidson and Girdwood²⁷ suggest that if clinical and hematologic responses do not occur within two weeks, it can be assumed that the disease being treated is not due to a deficiency of pteroylglutamic acid and that continued administration of the vitamin is contraindicated.

*LD₅₀ represents the amount of pteroylglutamic acid (mg. per kilogram of body weight) that will kill 50 per cent of the animals within the test period.

(To be concluded)

CASE 3341

PRESENTATION OF CASE

First admission A fifty-nine-year-old married Italian laborer was admitted to the hospital because of back pain.

Five months before admission the patient was first seen in the Out Patient Department because of pain in the left sacroiliac region, which had begun two and a half months previously while he was shoveling in a gravel pit. He admitted that similar brief attacks had occurred for about six months, but these had always cleared spontaneously. For the past two and a half months, however, the pain persisted despite strapping, heat, massage and rest. He also complained at bedtime of intermittent attacks of numbness over the outer aspect of the left thigh and an occasional sharp shooting pain from the left sacroiliac joint to the knee over the outer aspect of the thigh. He walked with a lump, used a cane and could produce only slight movement of the lumbar spine. An x-ray film at that time revealed moderate degenerative hypertrophic changes. There was no destructive or developmental abnormality. Conservative therapy was of no avail. The spinal fluid and a myelogram one month before entry failed to show any abnormalities. The patient continued to complain of the same difficulties and had lost 30 pounds of weight. During the week before entry a small nodule, 1.5 by 2.5 cm., appeared in the region of the upper third of the left sacroiliac joint and was firm and tender and caused reproduction of the referred pain and numbness along the anterolateral aspect of the left thigh.

Physical examination revealed that bending in any direction caused pain. Straight-leg raising was possible from 38 to 50° with tight hamstrings. Coughing and sneezing caused no pain. The reflexes were equal and hypoactive bilaterally in the legs. There was local tenderness over the lumbar and left sacroiliac regions. Recent weight loss was evident. The sclerae were slightly icteric. There was deep tenderness in the right upper quadrant, with a palpable liver edge 2 cm. below the costal margin on deep inspiration and the upper edge

percussed at the top of the sixth rib. A questionable, deep, irregular, poorly defined mass was noted in the right upper quadrant and right paraumbilical region. The spleen was questionably palpable.

The blood pressure was 160 systolic, 95 diastolic. Examination of the blood showed a red-cell count of 4,870,000, with 85 per cent hemoglobin, and a white-cell count of 8400, with 62 per cent neutrophils. The urine was normal.

Liver-function tests were negative except for a +++ cephalin-flocculation test in twenty-four and forty-eight hours and a van den Bergh reaction of 1.2 mg. per 100 cc. direct and 2.3 mg. indirect. A plain film of the abdomen revealed a liver somewhat smaller than that usually expected and a spleen within normal limits. A gastrointestinal series was normal. Barium enemas were not totally satisfactory because of pectenosis, but no definite abnormality was seen. Three weeks after admission the van den Bergh reaction fell to 0.5 mg. per 100 cc. direct and 0.9 mg. indirect. A cephalin-flocculation test was ++ in twenty-four hours and +++ in forty-eight hours. An intravenous pyelogram revealed normal kidneys, but the third lumbar vertebra at its left lateral aspect showed a loss of normal outline, with an irregular, moth-eaten appearance at this portion of the body, and the left transverse process suggested destruction. Also, there was loss of the articular facet on the left. The left psoas shadow appeared to bulge slightly opposite the lesion. No other destructive areas were seen. Alkaline and acid phosphatase levels were normal. An aspiration biopsy of the lumbar vertebra revealed a malignant tumor, unclassified, with a question of liposarcoma. X-ray therapy was instituted for relief of the pain with good success and some sclerosis of the lumbar vertebra. The patient was discharged two months after admission.

Final admission (two years later) He was seen in the Out Patient Department ten months after discharge, when there appeared to be no progression of the destruction of the left third lumbar vertebra but rather some evidence of further recalcification. A month later, however, the jaundice, which had disappeared for a while, recurred and began to increase. The patient developed lower abdominal pain, and his appetite became poor.

It was discovered on this admission that in his early youth he had been a heavy drinker, averaging 12 to 18 bottles of beer daily, with occasional wine or whisky for many years and irregular eating habits at that time. About thirty years previously he had had an attack of fairly marked jaundice with itching, which had subsided completely on medical treatment. Since then he had had occasional bouts of dark urine, and he believed that his eyes may have been yellow from time to time.

Physical examination disclosed an intensely icteric man with a smooth fine skin, rather sparse hair and scattered spider telangiectases over the

chest and back. The liver edge was palpable 7 cm below the costal margin. There was no evidence of ascites. The liver was questionably slightly nodular. There was slight tenderness over the lumbosacral joint.

The blood pressure was 134 systolic, 78 diastolic.

Examination of the blood revealed a red-cell count of 4,830,000, with 10.5 gm of hemoglobin, and a white-cell count of 4600, with 86 per cent neutrophils. The urine gave a + test for albumin, and the sediment contained cellular casts. The alkaline phosphatase was 13.7 units per 100 cc. The bromsulfalein test disclosed 100 per cent retention of the dye. The total protein was 7.68 gm per 100 cc, with 3.88 gm of albumin and 3.80 gm of globulin, the nonprotein nitrogen was 28 mg, and the fasting blood sugar 158 mg per 100 cc. A cephalin-flocculation test was ++++ in both twenty-four and forty-eight hours. The prothrombin time was 42 seconds (control, 15 seconds). The acid phosphatase was 1.5 units per 100 cc.

An x-ray film of the chest revealed evidence of old pleurisy at the left costophrenic angle and an area of increased density, 3 mm in size, in the left third interspace that might have been a blood vessel but could have been a small metastatic nodule. Marked arthritic changes were noted in the dorsal spine, a defect in the body of the third lumbar segment remained unchanged, and a soft-tissue mass still distorted the left psoas muscle. There seemed to be a mass in the epigastrium, which might have been the liver. In the hospital the prothrombin time rose, the patient developed guaiac-positive stools, and the nose began oozing blood. He developed complete anorexia to the point of nausea and had severe lower abdominal pain. He became anuric, and on the fifth hospital day the prothrombin time was 84 seconds against a 15-second control. On the sixth hospital day he developed a strong cholemic odor, became totally unresponsive and died.

DIFFERENTIAL DIAGNOSIS

DR WILLIAM CLARK It is quite apparent that this patient had severe liver disease and that involvement of that organ had been present, at least in recurrent form, for a thirty-year span. The terminal illness was one of liver failure, with associated renal involvement. In addition there was an episode of back pain, which was explained by the finding of a neoplasm involving the lumbar spine, two years before the final admission.

May we see the x-ray films?

DR MILFORD D SCHULZ The only available films of the spine are those made after x-ray therapy, so that I cannot say how the bones looked before treatment. The sclerosis that can be seen is probably the result of treatment. I can only point out the area of destruction in the third lumbar segment involving the small parts of the vertebra as well as

its body. The soft tissue in the left psoas region bulges and displaces the ureter. I do not know whether the shadow described in the lung represents a metastatic nodule or not. The only other thing that might be mentioned is the fact that these films of the esophagus are not adequate to allow one to say that the patient did not have varices. Nor does there seem to be a mass extending through the diaphragm from the liver.

DR CLARK We do not have the necessary films to help us determine the size of the liver or whether the mass was part of the liver. I should like to ask about the tumor. It is too bad that we do not have the older films. Are you reasonably certain that the tumor arose in the lumbar vertebrae and extended into the psoas region, or is it possible that it invaded the vertebrae from without?

DR SCHULZ I think that the latter is a possibility, but something arising in the vertebral body seems likelier. The whole affair could be a metastatic tumor.

DR CLARK Do you think that it is unusual for metastatic tumors of the lumbar spine to break through and invade into the soft tissue?

DR SCHULZ It is rare, but not impossible.

DR CLARK Primary tumors of the lumbar spine are not common. Most of the tumors of this area are metastatic lesions. I think we can safely assume that the predominant symptomatology at the first admission can be explained by the neoplasm. The pathological report of the nature of the neoplasm is difficult to evaluate. The tumor could not be definitely classified, as the pathologist stated, and I assume that it had many of the characteristics of a liposarcoma — a diagnosis that in itself, as I understand it, is usually made with some hesitation. At least in a case reported here in 1942,* Dr Mallory offered some apologies when he made the diagnosis of liposarcoma. Liposarcomas are reported to be radiosensitive, and I assume that there is good x-ray evidence that this tumor was radiosensitive. In addition, the symptoms improved. There is very little more that I can say about the diagnosis other than to accept it. The diagnosis is a reasonable explanation for the back pain. It is interesting that among the liposarcomas that are described, some start in a bone and invade the soft tissue and have been mistaken for soft-tissue tumors at operation. They are also said to be encapsulated. The problem is how to evaluate the tumor in relation to the liver disease.

The presence of both severe liver disease and a malignant tumor makes one want to conclude that this patient had a tumor in the liver, with metastases to the spine, or tumor of the spine metastasizing to or encroaching on the liver tissue and producing liver failure. I can find nothing in the protocol that will support either hypothesis, and I shall

*Case records of the Massachusetts General Hospital (Case 12057). *New Eng J Med* 226:204, 1942.

consider two separate diseases. The patient had had liver disease at twenty-nine years of age. I prefer to postulate two separate entities rather than two different types of liver disease. I shall try to develop the hypothesis that he had cirrhosis, that will make it easy to assume that the tumor did not metastasize to the liver, because we know that such metastasis does not usually take place.

In looking back through the record we have to deal with seemingly repeated episodes of jaundice, although we have only one clear-cut story. The history is also complicated by the fact that the patient consumed a large amount of alcohol. We do not associate alcohol consumption with acute episodes of hepatitis accompanied by jaundice, but rather with insidious changes characterized by fat being deposited in the liver that in some manner is related to nutrition. The best conclusion that we can draw regarding the episode of jaundice at the age of twenty-nine is that he had hepatitis of a cholangitic type as evidenced by the itching. Then we are told that following this he had episodes in which the urine was dark and that he probably had jaundice. I assume that these episodes were recurrences of the phenomenon that appeared at the age of twenty-nine.

He had jaundice at the time of the first admission to the hospital and at that time the liver was palpable but was not considered to be enlarged by the radiologist. Although one can conclude that he had some form of active liver disease, the tests performed at that time and the physical findings do not lead one to make a diagnosis of cirrhosis. After a remission of symptoms and physical signs he again exhibited signs of severe liver damage at the time of the final admission, and telangiectases or spider nevi were also found. The liver was described as enlarged and somewhat nodular, and I shall conclude that if nodules could be felt the liver was likewise firm. Even on the last admission, careful analysis revealed very little with which to make a diagnosis of cirrhosis of the liver. Perhaps the physical findings were the only things that definitely lead in that direction. The liver tests showed severe liver damage, but I do not believe that the tests in themselves imply cirrhosis. The repeated episodes of hepatitis with jaundice, which I believe to have been associated with cholangiolitis and eventual liver failure, make me want to explain the whole picture by a type of cirrhosis that developed in the course of recurrent cholangiolitic hepatitis. The concept of the recurrent type of cholangiolitic hepatitis and cirrhosis may not be generally acceptable but offers a good explanation of the sequence of events in this patient. I do not want to make a diagnosis of alcoholic cirrhosis, but we must admit that alcohol in some way influenced the liver damage. In other words, I do not believe that this picture will be that of alcoholic cirrhosis from the standpoint of the pathologist or a fatty

type of liver. The liver tests indicated terminal liver damage. The severe jaundice and the elevation of prothrombin time associated with the hemorrhage, the positive cephalin-flocculation test and so forth enable one to say that the patient died in liver failure. He developed terminal uremia, and nothing more about that can be said other than that he probably developed bile nephrosis.

I should like to conclude that he had cirrhosis associated terminally with an acute hepatitis, cholangiolitic in type, bile nephrosis and liposarcoma of the spine and the psoas region. I cannot say whether or not this tumor invaded the region of the liver because I do not have the evidence to make such a statement.

CLINICAL DIAGNOSES

Cancer of liver
Obstructive jaundice

DR. CLARK'S DIAGNOSES

Cirrhosis of liver
Bile nephrosis
Liposarcoma of spine

ANATOMICAL DIAGNOSES

Hepatoma, with invasion of cystic duct and metastasis to third lumbar vertebra
Cirrhosis of liver
Bile nephrosis
Arteriosclerosis, generalized, moderate

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: The slide of the biopsy in this patient was shown to a number of pathologists, and there was no general agreement concerning diagnosis. The outstanding feature of the histologic picture was a marked fatty vacuolization of the tumor cells, but on the other hand fat can be present in tumors for a number of reasons. The presence of fat does not prove that one is dealing with a liposarcoma. I did not see the slide until relatively recently and made a rather lucky guess on looking at it. I suggested that it might be a hepatoma. I know of a case in which the diagnosis of hepatoma was made from bone metastasis four years before the patient died and subsequently confirmed. In this case the interval was shorter but still significant—about two years.

Autopsy showed cirrhosis of the liver, which was rather finely granular in type, with a few large nodules and obvious invasion of the portal and hepatic veins with tumor thrombi—a characteristic behavior pattern of the primary liver-cell tumor. There was also involvement of the lymph nodes in the porta hepatis, from which the tumor had extended into the wall of the cystic duct and ulcerated so that fresh hemorrhage filled the biliary tract. The only other nodule of tumor found was in the lumbar vertebra, where it was originally seen by

x-ray study It was by that time a rather large tumor mass, which had destroyed a large part of the vertebra and had extensively invaded the psoas muscle on one side Microscopically, the tumor cells showed the usual arrangement seen in hepatomas, with numerous, huge tumor giant cells, which often contained 50 or 60 nuclei, a characteristic feature of primary tumor of the liver

DR CLARK Metastatic hepatoma of the spine must be unusual Would you say that that is true, Dr Mallory?

DR MALLORY The major metastases of hepatoma are by way of the blood stream rather than the lymphatic vessels, although local lymph-node involvement may occur The most frequent focus for metastasis under these conditions is naturally in the lungs In this case the tumor seems to have passed through the lung without causing a gross lesion Occasionally, as in hypernephroma, another blood-borne tumor, one sees similar bone metastases without demonstrable pulmonary lesions

A PHYSICIAN How often is this type of tumor found?

DR MALLORY: We used to consider it very rare Today it is not uncommon There are parts of the world where it is one of the most frequent tumors, especially South Africa and Java It is still relatively uncommon here One almost never sees it except subsequent to a long-standing cirrhosis. I think that as our treatment of cirrhosis improves and we keep patients alive longer and longer, we shall see this tumor with progressive frequency

DR M M SUZMAN In South Africa we have always found it associated with cirrhosis

DR MALLORY The only other notable relation is with fluke infestation

DR WILLIAM MCK JEFFRIES Is hepatoma as radiosensitive as the tumor in this case?

DR MALLORY I cannot answer that I do not believe that we have treated many hepatomas except in such terminal stages that there was no possibility of determining whether they were radiosensitive or not. Usually, by the time the diagnosis is made, the patient is almost moribund. Do you agree to that, Dr Schulz?

DR SCHULZ I think that we treat them only by accident.

A PHYSICIAN What is the explanation of the terminal uremia?

DR MALLORY That was a severe grade of bile nephrosis

CASE 33442

PRESENTATION OF CASE

A forty-eight-year-old housewife was admitted to the hospital because of pain in the back and weakness of both legs

The patient stated that as a young woman she had had pains in the lower back that sometimes

limited activity The pain was again pronounced when she was pregnant seventeen years previously Beginning six and a half years before entry there was almost constant pain on the left side in the lower back, hip, anterior aspect of the thigh and leg, heel, sole of the foot and in all five toes An operation for an intervertebral disk at the fourth and fifth lumbar region was performed five years before entry. The patient was free from pain until she started working again as a pianist, four months after the operation, when the same pain returned, steadily increasing in severity, and was shortly accompanied by some dragging of the left leg One month before admission the right leg became weak The weakness of both legs increased, and on admission the patient was able to walk only by using a cane and with the help of another person Slight difficulty in voiding had been present for several days

Physical examination revealed a well nourished woman in no obvious discomfort The heart and lungs were normal There was a low lumbar midline scar Both legs were weak and spastic, the right more so than the left The feet could be dorsiflexed just short of right angles The knee jerk was absent on the left and present on the right There was bilateral ankle clonus Abdominal reflexes were absent, and ankle jerks were brisk, the plantar reflexes were extensor Pain, touch and temperature sensation were impaired on the legs, posterior portions of the thighs and saddle area, but no sharply defined sensory level was demonstrated There was diffuse tenderness over the lumbar spine and sacrum

The urine had a specific gravity of 1.002, and the sediment contained occasional pus and epithelial cells Examination of the blood disclosed 13.8 gm of hemoglobin and a white-cell count of 8300

A spinal puncture was performed in the third lumbar interspinous space On jugular compression the pressure rose slowly from 150 to 350 mm of water and fell very slowly to 250 mm when compression was released The protein was 204 mg per 100 cc X-ray examination showed an operative defect in the upper margin of the left lamina of the fifth lumbar vertebra, and degenerative changes about the smaller articulations between the fourth and fifth lumbar vertebrae

A myelogram was done on the second hospital day The oil passed up to the body of the twelfth thoracic vertebra, where it was completely arrested, ascending slightly higher on the right and forming a fairly good "cap" (Fig 1) On the fourth hospital day an operation was performed

DIFFERENTIAL DIAGNOSIS

DR ARTHUR L WATKINS May we see the x-ray films?

DR TOUFIC KALIL There is no mention in the abstract of the fracture of the seventh thoracic

vertebra, and the myelogram shows this round irregular defect with complete blockage at the level of the twelfth dorsal vertebra. Reference to the other end of the Pantopaque column is seen here, with the block at the lower end, occurring at the fifth lumbar interspace, and with some irregularity of the lamina on the left, probably from the old operation.

DR WATKINS: Do you see any evidence of destruction of the vertebra at the twelfth dorsal vertebra?

DR KALIL: No.

DR WATKINS: We have a history of intermittent complaints relative to the back, extending over a long period, with an increase in symptoms during pregnancy. The character of the pain became persistent about six and a half years before the final episode. At the time of the first operation there were sensory symptoms referable to the lower lumbar and first sacral segments, and presumably on this basis the operation was done for a protruding intervertebral disk. We do not have any further information about what was found, but we do know that as soon as activity was started again the pain returned, and for the first time we find evidence of definite involvement of the motor system, manifested by a dragging of the left leg. We should like to know what was the type of weakness—whether it was on the basis of anterior-root involvement, that is, the lower motor neuron type of weakness, or due to disease in the spinal cord, with some spasticity present, again, we can only guess about that. What finally brought the patient to the hospital was increase in pain and involvement of the opposite extremity.

Physical examination made it perfectly evident that we must go higher than the site of the previous operation to explain the physical signs: the spastic type of weakness, with Babinski response, ankle clonus and absent abdominal reflexes. A spinal puncture was done above the level of the previous operation, and there was block higher up as judged from the dynamics and also increased protein, so that we now look for a lesion in the lower part of the spinal cord. Although the sensory level was not very accurate, we suspect clinically from the physical findings involvement presumably of the first sacral segments, and we localize a lesion right at the end of the spinal cord to explain the present complaints.

Regarding the etiology of such a lesion, first of all we might consider the long history of back pain. This may simply have been a poor back mechanically. It is difficult to interpret from the x-ray film after the operations what sort of fault was present in the lumbosacral region. Frequently in pregnancy a patient with rheumatoid arthritis gets increase in back pain, but the sacroiliac films do not show any evidence of it, and we would expect after all these years to have definite x-ray evidence

if it had been due to rheumatoid arthritis. This patient may have had pain for mechanical reasons and a ruptured disk to explain some of the symptoms, but the picture of a slowly increasing involvement of the spinal cord cannot be reasonably explained by a ruptured disk. I do not know how to link up what appears to be an old compression fracture in the dorsal area. We have no history of trauma above the level of the lesion that seemed to

FIGURE 1

be producing the symptoms, so that I am inclined to overlook that because there is no x-ray evidence of neoplasm.

Considering infection as a possible cause, we have nothing to suggest syphilis. Tuberculosis can of course cause spinal-cord compression, but if it were of such long standing we would expect a soft-tissue mass and some bony changes, which were absent, and I therefore think that we can rule out tuberculosis. Another possibility is arachnoiditis, which is sometimes given credit for intermittent and prolonged symptoms in numerous areas, but I would not expect it to cause an x-ray picture such as this, with so definite a block at one level. Again, arachnoiditis is not too satisfactory a pathological

diagnosis, and I do not believe that that is the answer in this case

That leaves us with tumor of some sort as the most probable diagnosis. This was a slowly growing tumor with a history of at least six years' duration. If we localize it at the end of the spinal cord we can only guess what type of tumor it might have been. There is no evidence of metastatic disease or primary bone tumor, so far as I can see. I shall choose as my first guess an ependymoma of the conus or filum, which is slowly growing, or possibly a meningioma.

DR AUGUSTUS ROSE: Do you think that she had a ruptured intervertebral disk?

DR WATKINS: Yes, she may have had a ruptured disk, but I doubt whether it was responsible for the complaints, particularly if the weakness was spastic and developed immediately after operation.

DR ROSE: Was a myelogram done before the operation for ruptured disk?

DR CHARLES S. KUBIK: No, it was not.

Dr Ballantine, will you describe the operative findings?

DR H. THOMAS BALLANTINE, JR.: This patient was operated on under nitrous oxide, oxygen and ether anesthesia, and a laminectomy was done including the tenth, eleventh and twelfth dorsal vertebrae just above the conus of the cord. The cord was found to be considerably widened, owing to diffuse swelling, more on the left than on the right, bearing out the x-ray findings that the block started slightly lower on the left side than on the right. I shall quote part of the operative note because it is interesting: "On opening of the dura the tumor could be seen bulging from the left posterior surface of the cord as a rounded purple-pink mass. There was considerable fusiform swelling of the cord above and below the tumor." The tumor seemed to start in the substance of the cord and seemed at first to be an intramedullary glioma, although against that was the fact that there was a discrete mass, which was removed almost as a dumbbell-shaped tumor. We got part of it out—a piece measuring about 1.5 cm in diameter—and thought that that was all until further dissection showed below this layer another mass 2 cm in diameter. At the time of operation there was no clue regarding the point of origin of this new tumor mass.

DR KUBIK: What is the present condition of the patient?

DR BALLANTINE: Postoperatively she had difficulty in voiding and marked increase in weakness in the legs. A week after operation these symptoms began to clear, and she developed fairly good tone in the right leg beginning at the ankle and the toes and some extension and dorsiflexion. The left leg was much slower in returning to normal. On intensive physiotherapy she reached the point where at discharge from the hospital, approximately a month later, she was able to bear weight on the left leg and quadriceps function was returning. I think that she will walk. The plantar signs cleared, and she had only occasional incontinence at night and was never incontinent during the day.

CLINICAL DIAGNOSIS

Tumor of spinal cord, eleventh dorsal region

DR WATKINS'S DIAGNOSIS

Ependymoma of conus?

Meningioma?

ANATOMICAL DIAGNOSIS

Meningioma of spinal cord

PATHOLOGICAL DISCUSSION

DR KUBIK: I suppose that it would be difficult to say whether or not this patient had a ruptured disk at the time of the original operation. The pain was the type caused by ruptured disk, and I should say less commonly observed with lesions as high as this. It seems likely that in this case the symptoms were caused by the tumor. The case illustrates the importance of careful clinical investigation.

DR BALLANTINE: There is some evidence that this tumor was responsible for all the symptoms in that the back pain, of which the patient had complained for six and a half years, was relieved soon after the operation.

DR KUBIK: The tumor was a meningioma. At operation it was thought that ependymoma was the more probable diagnosis. This is a common site for ependymomas, arising in the lower part of the cord or conus. Dr W. Jason Mixter, as I understand it, did not find any attachment to the dura.

DR BALLANTINE: No attachment was found.

DR KUBIK: Histologically, the tumor was a typical meningioma.

CHILD HEALTH SERVICE FOR STUDENT VETERANS

PLANS for the care of approximately 1500 children of student veterans at Harvard have finally matured and were put into operation in mid-September. The project, which has been under consideration for a year or more, is based primarily on an urgent pediatric need. There have been at Harvard for the past two years, living in student housing facilities in Cambridge and at Harvard Village in

Ayer, some 3000 GI families from all parts of the country, subsisting mainly on government allotments insufficient to provide adequate medical care for their children. This unusual concentration of infants and children, moreover, was beginning to overtax the medical facilities of the community and contained the possibility of serious difficulties in case disease should appear in epidemic proportions.

The need and the danger have been apparent to Dr. Arlie V. Bock, professor of hygiene at Harvard University, who enlisted the aid of Dr. Allan M. Butler, chief of the Children's Medical Service at the Massachusetts General Hospital and professor of pediatrics at Harvard Medical School. The plan that has gone into operation resulted.

Two health centers for the children involved have been opened, one in Cambridge and one in the Lovell General Hospital at Fort Devens. At these centers, under the direction of Dr. Francis C. McDonald, medical service, comprising physical examinations, immunizations, diagnosis and treatment, is being provided at federal expense. Home service is provided as needed, including consultation visits by pediatricians who are licentiates of the American Board of Pediatrics.

Harvard University provides clinic and office space, the Massachusetts General Hospital furnishes administrative services and clinical facilities and personnel, and the Massachusetts Department of Public Health aids in the administrative program, supervises the public-health nursing and provides consultative service on nutrition and medical social problems.

Last but not least, funds, based on a cost of \$35 per patient per year are being provided by the Children's Bureau of the United States Federal Security Administration, via the Massachusetts Department of Public Health. These funds are available on the stipulation that they shall be used for a study as well as for a service project.

The service project has been outlined above. The study will consist largely in the collection and compilation of "statistics on the cost of providing complete health and medical care for infants and children as well as on the incidence of various illnesses and the kinds of service required." As such it should prove to be a valuable complement

to the survey of pediatric facilities of the country that has been undertaken by the American Academy of Pediatrics and is now drawing to its close

There appears to have been launched, under excellent auspices, a particularly worthy government-financed project. Only one similar program has been conducted, that which was under way last year at the University of Washington, in Seattle. The medical profession at large should heartily approve of such a public-health and fact-finding undertaking.

STREPTOMYCIN IN BACTERIAL ENDOCARDITIS

CASES of bacterial endocarditis, irrespective of their etiology, were almost universally fatal prior to the introduction of the newer chemotherapeutic and antibiotic agents. The use of sulfonamides has resulted in cures only in rare cases. On the other hand, there is now a considerable body of evidence to show that penicillin is highly effective in the treatment of most cases of subacute bacterial endocarditis and has also produced cures in an appreciable proportion of cases of acute bacterial endocarditis due to penicillin-susceptible organisms.

There remains, however, a group of cases of acute and subacute bacterial endocarditis due either to streptococci that are relatively insensitive to penicillin or to gram-negative bacilli, which are quite resistant to the action of that antibiotic. Most of the latter organisms and some of the former are susceptible, at least in vitro, to streptomycin. It therefore seems reasonable to attempt prolonged and intensive streptomycin therapy in such cases.

The ease with which resistant variants appear in patients with various infections during the course of treatment with streptomycin, thus nullifying the effects of that antibiotic, and the nature of the lesion in cases of bacterial endocarditis may give rise to reasonable doubts concerning the effectiveness of prolonged and intensive treatment with streptomycin, particularly since irreversible deafness and vestibular damage occur in most cases. Such therapy can be justified, even in such a fatal disease, only if there is a reasonable expectation of cure of the underlying infection in a significant proportion of cases.

It is therefore gratifying to have a report summarizing the results of the use of streptomycin in the treatment of bacterial endocarditis. Hunter¹ reviewed the cases that have been treated at the Presbyterian Hospital, together with those collected by Dr. Chester S. Keefer and the Committee on Chemotherapeutic and Other Agents of the National Research Council. Of a total of 18 patients with bacterial endocarditis treated with streptomycin, 8 appeared to be cured. The cures included 4 of 8 cases in which a gram-negative bacillus was involved, 1 of 5 cases due to enterococci, 2 of 4 cases in which *Streptococcus viridans* was the organism and 1 case due to *Staphylococcus aureus*. Penicillin was also used, apparently without success, in the cases in which the gram-positive organisms were involved, and sulfonamides were used in some of the cases. One additional case of bacterial endocarditis due to a parainfluenza bacillus and apparently cured by streptomycin has recently been reported from the Massachusetts General Hospital.²

In some of the cases included in Hunter's report, failures were probably the result of treatment that was inadequate or was begun late in the course of the disease. The fact that an appreciable percentage of cases resulted in cures, however, indicates that streptomycin therapy is warranted in all cases of bacterial endocarditis due to gram-negative bacilli and in those due to other organisms that are sensitive to streptomycin in which the patient fails to respond to penicillin. The results in these cases also emphasize the importance of careful bacteriologic control in the management of such cases.

MASSACHUSETTS MEDICAL SOCIETY DEATHS

NELSON — Christian A. Nelson, M.D., of Cambridge, died on September 21. He was in his seventy-fourth year. Dr. Nelson received his degree from Harvard Medical School in 1911. He was a former member of the Massachusetts Medical Society. His widow survives.

UNDERHILL — Elizabeth C. Underhill, M.D., of Poughkeepsie, New York, died on September 20. She was in her seventy-seventh year. Dr. Underhill received her degree from Cornell University Medical College in 1900. She was resident physician at Mt. Holyoke College for thirty-seven years.

ELLIOTT CARR CUTLER (1888-1947)

Elliott Carr Cutler was born in Bangor, Maine, on July 30, 1888, the son of George Chalmers Cutler and Mary Wilson Cutler. After his graduation *cum laude* from Harvard Medical School in 1913 he spent some months in Dr. Frank B. Mallory's laboratory, and then studied at the University of Heidelberg. He was surgical house officer at the Peter Bent Brigham Hospital from 1913 to 1915, and then resident surgeon at the Massachusetts General Hospital.

Dr. Cutler served in France in 1915, with the Harvard Unit, before the United States entered the war, his second tour of duty began in May, 1917, when he again went to France with Base Hospital No. 5. He was promoted to the rank of major in November, 1918, and received the Distinguished Service Medal.

On his return to the United States Dr. Cutler was resident surgeon at the Peter Bent Brigham Hospital from August, 1919, to September, 1921, associate in surgery at the hospital and chairman of the Department of Surgery, Harvard Medical School. In 1924 he was called to the professorship of surgery at Western Reserve University School of Medicine, Cleveland, where, in addition, he was director of the Surgical Service of the Lakeside Hospital. In 1932 he was chosen to succeed Dr. Harvey Cushing as Moseley Professor of Surgery at the Harvard Medical School and surgeon-in-chief of the Peter Bent Brigham Hospital.

Before the United States entered World War II, Dr. Cutler reorganized General Hospital No. 5, with which he had served in 1918. He was chief surgical consultant of the European Theater of Operations from August, 1942, to February, 1945, when he became Chief of the Professional Services Division in that Theater. He was promoted to a brigadier-generalship in June, 1945, and received an Oak Leaf Cluster to the Distinguished Service Medal already awarded. He was made honorary officer of the Most Excellent Order of the British Empire and received the *Croix de Guerre* with palm from the French Government and the Haakon VII Liberation Cross from the King of Norway.

At the time of his death he was president of the American Surgical Association — perhaps the highest honor that can be granted to any American surgeon. In 1947 he received the Bigelow Medal from the Boston Surgical Society. He was a member of the Society of Clinical Surgery, the New England Surgical Society, the American Association for Thoracic Surgery, the American Committee for the Protection of Medical Research,

the Society for Experimental Biology and Medicine and the American Society for Clinical Investigation and honorary member of surgical societies of France, Italy and Belgium and was given honorary fellowships in the Royal College of Surgeons of England, the Royal College of Surgeons of Edinburgh and the Royal Society of Medicine of England. He had received honorary degrees from the University of Strasbourg, the University of Vermont and the University of Rochester.

He was on the editorial boards of the *Journal of Clinical Investigation*, the *American Journal*

of Surgery, the *American Heart Journal* and the *British Journal of Surgery*.

The obituary notice of the *British Medical Journal* (August 23, 1947) contained the following note, written by his friend and associate, Sir Gordon Gordon-Taylor: "Elliott had always driven the chariot of his busy, feverish life with rein unchecked, not one moment of the day wasted, no evenings 'steeped in homed indolence'. Even when the truth of his mortal illness came 'naked and sabre-like' against his great heart the pace of life never slackened. There was no neglect of the surgical direction of his hospital, he travelled all over the wide areas of the United States of America in his supreme desire that the surgical arrangements and the surgery for the veterans of the recent war should be the very best. The term 'deputy' found no place in his vocabulary. No complaint of the unkind blow of Fate ever passed his lips, the courage of the man evoked admiration on every hand."

CORRESPONDENCE

CONTRACEPTIVE CARE TO MARRIED WOMEN

To the Editor An initiative petition seeking adoption of "An Act to Allow Physicians to Provide Medical Contraceptive Care to Married Women for the Protection of Life or Health" was filed the end of July, 1947, by the following petitioners: Karl T. Compton, president of Massachusetts Institute of Technology, Dr. Nathaniel W. Faxon, medical director, Massachusetts General Hospital, Dr. Robert H. Goodwin, obstetrician-in-chief, St. Luke's Hospital, New Bedford, Dr. Frederick C. Irving, professor emeritus of obstetrics, Harvard Medical School, Henry P. Kendall, of Sharon, president of Kendall Company, Dr. Samuel A. Levine, assistant professor of medicine, Harvard Medical School, Mrs. Arthur Devens Potter, of Greenfield, past president, Massachusetts State Federation of Women's Clubs, Dr. John C. Rock, clinical professor of gynecology, Harvard Medical School, Mrs. Arthur G. Rotch, former president of Massachusetts League of Women Voters, and Dr. George M. Shipton, chief of Obstetrical Department, House of Mercy Hospital, Pittsfield.

In submitting the petition, President Compton made the following statement:

I believe that the public interest can best be served by placing in medical hands the control of medical matters. The giving of contraceptive care is a generally accepted medical technique which should not be denied by law to anyone whose medical need is great. Those needing and desiring contraceptive help should not be either left in complete ignorance or left at the mercy of irresponsible sources of information. Naturally, such information and help should not be forced upon anyone whose religious beliefs are opposed to those measures, but by the same token the religious beliefs of some should not be forced upon all. This is an elementary matter of civil liberties in a democracy.

With this statement I am in entire accord.

The petition has been approved by the Attorney General as to form and substance, and a minimum of 20,000 certified signatures of registered voters must be obtained this fall. The measure then goes to the Legislature, which must act by roll-call vote before June, 1948. If not enacted into law by the Legislature, the measure goes on the 1948 ballot as a referendum after the collection of a minimum of 5000 additional signatures.

A similar measure was rejected by a small margin of voters in 1942 after a vigorous campaign that aroused widespread interest and resulted in a larger number of votes being cast than on any previous referendum. At that time, the Massachusetts Supreme Judicial Court, in an advisory opinion, stated that such a measure was "purely permissive (and) will not interfere with the freedom of any person within its scope to act in strict accordance with his religious views."

Only Connecticut and Massachusetts now prohibit doctors from prescribing contraception for their sick patients, al-

though the American Medical Association and other medical groups have recognized the procedure as an integral part of preventive medicine.

I urge all physicians to support this measure and to help in obtaining the necessary number of signatures.

AEROSOL THERAPY OF RESPIRATORY DISEASE

A Report of Fifty Cases

VERNON BRYSON, PH D,* AND EDWIN J GRACE, MD†

COLD SPRING HARBOR AND BROOKLYN, NEW YORK

AEROSOL therapy may be defined as the medicinal administration of fine solid particles or liquid mists as inhalants. The method has never been widely used in the treatment of disease, although asthmatic patients have been given symptomatic relief with epinephrine aerosols for many years. To anyone familiar with the basic studies on the subject,¹⁻⁷ the administration of antibiotics as aerosols appears to be a logical and necessary development. It may be anticipated that the advantages of simple administration and a relatively constant rate of absorption will eventually induce medical investigators to explore more fully the process of aerosolization as a technic for giving antibiotics, chemotherapeutic agents, enzymes, antibodies, endocrines, radiologically opaque solutions, bacteriophage, radioactive isotopes and many other diverse chemical materials.

From early in the war until recently, one of us (V B) was engaged in research‡ on the physical and biologic properties of aerosols for the Technical Division, Office of the Chief, Chemical Warfare Service. Publication in 1944 of a report on the production of penicillin aerosols and their inhalation by animals and man stimulated the interest of clinicians in the application of antibiotic mists for the treatment of pulmonary infection. Further studies were pursued for the Technical Division on a co-operative basis with the College of Physicians and Surgeons of Columbia University and later under contract to the Medical Division, Chemical Warfare Service. In addition, we have carried on an independent program resulting in the accumulation of clinical data on the use of aerosols in the treatment of respiratory infection. This work is reported below.

Considerable knowledge has been gained recently on the clinical application of penicillin aerosols,

notably by Olsen,¹⁰ Barach et al,¹¹ Vermilye,¹² Segal and Ryder,¹³ Humphrey and Joules¹⁴ and by Southwell.¹⁵ It is now known that blood levels well above the minimum bacteriostatic requirement to inhibit the growth of nonresistant staphylococci and streptococci can easily be obtained.¹¹ The presence of penicillin in the blood and urine after penicillin aerosol therapy may justifiably be regarded as proof that the antibiotic is being absorbed.⁹ The attainment of high blood levels at the expense of unduly complex rebreathing apparatus and accessory equipment, however, does not seem to us a warranted procedure, except when demonstrably more effective clinically. Segal and Ryder¹³ have obtained striking clinical improvement in 2 cases in which no blood level could be demonstrated after aerosol therapy. Their conclusions that blood levels are mainly of academic interest rather than practical value and that the clinical course of a disease should be the criterion of effective treatment are probably justified.

At the present time a trend to the use of increasingly complex accessory equipment in the production and administration of therapeutic aerosols is apparent.^{16, 17} The value of complex baffles, valves and rebreathing devices is problematical. Actually, all that is needed to administer aerosol therapy is a suitable nebulizer,§ a source of compressed air or oxygen and a rubber tube. Insertion of a Y tube or small hole in the tubing connecting the oxygen tank and nebulizer enables the patient to operate the nebulizer only during inhalation by placing his finger over the open end of the Y tube or hole in the rubber tube.^{11, 18} A small electrically motivated air compressor may be used as a substitute for tank oxygen, provided that the air is carefully filtered to remove any machine oil and that supplementary oxygen is not required.¹⁴

At the outset we were convinced that if penicillin aerosol therapy was to be a generally useful thera-

*Research biologist, Long Island Biological Society, Cold Spring Harbor, New York.

†Clinical director, Hittington Hospital; associate attending physician, St. John's and Brooklyn hospitals.

‡This study was aided by a grant from the Josiah Macy Jr., Foundation.

§Vaporocentrifuge—obtainable from Vaporocentrifuge Company, Upper Darby, Pennsylvania.—or DeVilbiss 40—obtainable from DeVilbiss Company, 111 Eighth Avenue, New York City.

peutic method, simplicity of equipment and procedure was vital. By means of a nebulizer (for which the ordinary unbaffled atomizer is not a substitute), the patient inhales aerosolized penicillin either through cannulae passing into the nose or by mouth, depending on the clinical problem involved. When possible, deep inspiration on the part of the patient aids in the maximum distribution and retention of aerosol. Our subsequent experience, as well as that of Olsen¹⁰ at the Mayo Clinic, has demonstrated the value of a simple technic.

At the same time it is necessary to select the necessary minimum of equipment with care. Experimental evidence indicates that to penetrate to the smaller bronchioles and alveoli of the lungs, aerosols must be composed of small particles, on the order of magnitude of 5 microns in diameter or less.¹⁹ Large particles are impinged by convection in the nose, throat and upper respiratory passages and are undesirable, except for the treatment of infectious tracheitis, laryngitis and other diseases of the larger respiratory passages or for mucosography.²⁰ Therefore, the clinician must distinguish between the ordinary commercial atomizer, which produces relatively large droplets on the principle of a flit gun, and the nebulizer. A nebulizer is constructed with some intermediate baffle interposed between the spray jet and the orifice, larger particles impinging on this baffle are broken into smaller droplets and expelled, or returned by gravitational force to the main reservoir for recirculation. Even some commercial nebulizers produce a considerable percentage of large particles, which merely means that a greater proportion of the inhaled solution is delivered to the surface of the throat, larynx and trachea. The treatment of respiratory disease may, in fact, be accomplished by an ordinary atomizer, as reported by Morse.²¹ In this event the principal effect on alveolar or bronchiolar surfaces is achieved topically by the fraction of small particles present in an atomized spray, together with an indirect systemic action of material absorbed from epithelial surfaces of the upper respiratory tract. The method is suitable for nontoxic substances, but if Promin^{22, 23} or similar materials are to be used further for topical aerosol therapy of the lower respiratory system, the spraying of atomized solutions is contraindicated as producing physically heterogeneous aerosols, a large component of which would contribute to systemic toxicity without reaching the alveolar surfaces. If it is desired to confine therapy predominantly to the bronchioles and alveoli, the clinician should ascertain that the nebulizer of his choice produces with 5 per cent glycerin a fine smoke that floats in the air, rather than a spray capable of wetting objects placed a few inches from the orifice. A convenient test is to direct the nebulizer at a pane of glass adequately warmed to prevent undue condensation. Physical analysis of aerosols

produced with nebulizers considered clinically efficient for treating pulmonary disease reveals a modal particle diameter of 1 or 2 microns. Particles of this size will reach the peripheral respiratory branches.

Inhalation of aerosolized penicillin is a form of topical application. Florey and Fleming at an early date emphasized the importance of the topical use of penicillin whenever possible, a point reiterated by Florey at the Twenty-First Clinical Congress of the Connecticut State Medical Society in September, 1946. In other reports the topical administration of high concentrations of penicillin combined with the anionic detergent, Aerosol OT (dioctyl ester of sodium sulfosuccinate), in the successful treatment of chronic osteomyelitis is described.²⁴⁻²⁶ In the present study 34 subjects were treated with aerosols of the cationic detergent Zephiran (alkyl dimethyl benzyl ammonium chlorides in aqueous solution), employed as a solvent for antibiotics. In the treatment of any chronic disease, whether pulmonary infection or osteomyelitis, the existence of infective foci sheltered from the effects of routinely administered penicillin by fibrosis, purulent matter or avascularity is a serious problem. The local use of antibiotic solutions in combination with detergents whose pharmacology and toxicity have been studied^{27,28} is based on the following primary considerations:

Antibiotics administered in detergent solutions may possess the obvious advantages associated with detergency: emulsifying properties and reduced surface tension. The breaking up of pus and cellular detritus in solutions of wetting agents has been shown by Palitz and Herman.²⁹ Detergents are employed in the treatment of empyema, ulcers and infected fractures and routinely for the disinfection of skin and mucous membranes. In the aerosol treatment of fibrosed and purulent areas of the respiratory tract by antibiotics it is evident that any substance that might increase the probability of effective bacteriostatic contact between micro-organism and the antibiotic is a desirable adjuvant.

The activity of both penicillin and streptomycin *in vitro* is synergistically enhanced by the presence of detergents. In fact, it has long been known that detergents may enhance the action of bactericidal and bacteriostatic agents generally.³⁰ Excluding detergents, we have observed a definite synergism of penicillin with 9-aminoacridine hydrochloride and streptomycin, using *Staphylococcus aureus* among other test organisms. The wetting agents Aerosol OT and Zephiran Chloride also potentiate the activity of penicillin *in vitro*, although the effect is reduced in the presence of blood.³¹ The activity of Zephiran with penicillin on *Staph. aureus* (strain 313, N R R L) is shown in Table 1. Viable organisms

were determined by dilution platings of samples taken from tryptose phosphate broth at one, six and twenty-four hours of growth at 37°C.

It is observed that in the presence of a combination of Zephiran and penicillin (at concentrations singly ineffective in checking the growth of *Staph aureus*) the surviving bacteria have been reduced in number to less than 0.1 per cent (Table 1). In solid mediums the same concentration of Zephiran uncombined with penicillin reduces surviving bacteria to 2.5×10^4 per million (Zephiran, 1,700,000). A level of penicillin is chosen that reduces survivors to 10^4 per million (penicillin, 0.01 units per cubic centimeter). In

resistant organisms serve to complicate the problem of treatment and become a potential source of new infections that are resistant from the onset. Therefore, in all use of antibiotics in which selection to resistance may occur, it is most urgent to use a dose that will be effectively bacteriostatic for all organisms, including any that may have mutated to the initial step in the development of resistance. Antibiotics should be administered in large doses and with sufficient frequency to maintain bacteriostasis for the more resistant members of a heterogeneous bacterial population. When possible, local therapy should be instituted. The problem of drug fastness, of

penicillin-detergent combinations there are no survivors among 6.4×10^4 seeded bacteria.

Although an undeniable gap exists between clinical results and animal experimentation it is perhaps significant that in investigations conducted for the Medical Division, Chemical Warfare Service, it was observed that the administration of penicillin and Zephiran aerosols to mice with experimental pulmonary disease results in a reduction of mortality compared with penicillin aerosol controls.

Antibiotic-detergent therapy, like multiple chemotherapy generally, may be instrumental in reducing the incidence of refractory drug-fast infection incurred during the course of treatment. Our colleague, Demerec,²² has shown that among staphylococci (and presumably among most other ordinarily susceptible bacteria) penicillin resistance occurs spontaneously in the absence of penicillin by a process of mutation among a certain proportion of penicillin-susceptible organisms undergoing multiplication. The same considerations apply to streptomycin.²³ We believe that the insidious appearance of resistant bacterial strains during a therapeutic program may be assumed to depend on a process of artificial selection *in vivo*. This involves the elimination of susceptible bacteria and the survival of their more hardy mutant descendants to form an ensuing generation of resistant pathogens. Surviving as a result of inadequate therapy, these

debated significance in clinical treatment with penicillin, appears destined to be of greater importance with increased use of streptomycin.^{24, 25} On a genetic basis the likelihood that resistance will be developed by a micro-organism against two bacteriostatic agents used simultaneously is very small, being the product of two arithmetic fractions. These fractions represent the probability of resistance (mutation) occurring to protect the organism from either substance alone. If the interesting observations of Carpenter et al.²⁶ and our own studies on synergism can be interpreted in this manner, the use of multiple chemotherapy takes on particular significance and may prove to become an urgent necessity in the use of agents that depend on subtle metabolic mechanisms for their activity.

We are well aware that the use of antibiotic aerosols, particularly in combination with synergistic agents, is largely unexplored. The germicidal effects of wetting agents may be partially nullified by foreign materials^{27, 28} or by variation in hydrogen ion concentration.²⁹ For this reason the principles expressed must be regarded primarily as working hypotheses. Our own clinical experience over a period of two years in the treatment of osteomyelitis and respiratory disease, however, leads us to believe that consideration of the accumulated case histories previously reported and presented below may lead to a wider clinical employment of multiple chemo-

TABLE 2 Summary of Cases of Bronchiectasis, Bronchitis, Sinusitis and Miscellaneous Infections Treated with Penicillin Aerosol *

	DIAGNOSIS	DURATION OF TREATMENT da.	TREATMENT	DURATION OF ILLNESS	ORGANISMS RECOVERED	COMMENT
	Bronchiectasis	18	50,000 units of aerosolized penicillin dissolved in physiologic saline solution every 24 hr	Since childhood	Nonhemolytic <i>Staph aureus</i>	No improvement after follow up in 1 yr no 2nd-yr follow-up available
	Chronic bronchiectasis	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	14 yr	Beta-hemolytic streptococcus and hemolytic <i>Staph aureus</i>	Patient shows marked improvement, particu- larly to this year, when given larger dosage
	Emphysema, with lung abscess, secondary to pneumonia	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	4 yr	No cultures	Patient seen in October, 1946, and showed evidence of parenchymal damage
M	Chronic bronchitis, with hemoptysis		100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	1 yr	<i>Escherichia coli</i>	Marked improvement, expectoration dimi- nished from 180 to 4 cc per day
F	Chronic bronchitis, with chronic sinusitis	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	5 yr	<i>Staph aureus</i> predominantly, <i>Esch coli</i>	Marked improvement, recent severe cold cleared up with routine bed rest, no exces- sive expectoration
F	Post-virus pneumonia, questionable Boeck sar- cold with diffuse oedema infiltration	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	6 wk	<i>Esch coli</i> , beta-hemolytic strepto- coccus, hemolytic <i>Staph aureus</i> and <i>Monilia albicans</i>	Patient, graduate nurse who stated that she had contracted virus pneumonia from pa- tient, was acutely ill and responded satis- factorily
7 43 F	Chronic bronchitis, with chronic sinusitis	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	3 yr	<i>Bacillus subtilis</i> and hemolytic <i>Staph albus</i> in sinus drainage, <i>Staph albus</i> , predominantly, in sputum	Complete recovery when seen in June, 1946, headaches associated with chronic sinusitis had entirely disappeared
8 33 F	Chronic bronchitis, with chronic sinusitis	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	10 yr	Hemolytic <i>Staph albus</i> and <i>B subtilis</i>	Patient made good recovery and has no symptoms at present
9 29 M	Acute exacerbation of chronic sinusitis	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	8 yr	Nonhemolytic streptococcus	Excellent result, prior to aerosolization patient had many operative procedures for sinus drainage, swelling in eyes entirely subsided
10 36 F	Chronic bronchitis, with bronchiectasis	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	4 yr	Alpha-hemolytic streptococcus (viridans group)	Patient has made excellent improvement to date, but follow up inadequate owing to brevity of time since treatment
11 45 F	Chronic bronchitis, with chronic sinusitis	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	20 yr	Nonhemolytic <i>Staph albus</i> in sinus drainage	Improvement to date excellent, but 2 months' follow-up too limited for final opinion
12 65 F	Chronic bronchiectasis, with emphysema	10	50,000 units of aerosolized penicillin dissolved in physiologic saline solution every 24 hr	15 yr	Beta-hemolytic and alpha-hemo- lytic streptococcus, staphylococ- cus, <i>Esch coli</i> and <i>Pseudomonas aeruginosa</i>	Patient unimproved
13 67 M	Bronchiectasis	10	50,000 units of aerosolized penicillin dissolved in physiologic saline solution every 24 hr	10 yr	Nonhemolytic <i>Staph aureus</i> , non- hemolytic <i>Staph albus</i> and <i>Klebsiella pneumoniae</i> (Type B)	Temporary improvement following treatment, patient now has recurrence and has been advised to have streptomycin treatment in view of gram-negative organisms
14 30 F	Chronic diffuse bron- chiectasis, with healed tuberculous	6	100,000 units of aerosolized penicillin dissolved in physiologic saline solution every 24 hr	11 yr	Hemolytic <i>Staph aureus</i> , hemo- lytic streptococcus, <i>M. albicans</i> and <i>K. pneumoniae</i> predomi- nantly	Patient unimproved
15 67 M	Bronchiectasis	5	100,000 units of aerosolized penicillin dissolved in physiologic saline solution every 24 hr	Since childhood	Beta-hemolytic streptococcus, hemolytic <i>Staph aureus</i> and alpha-hemolytic streptococcus	Temporary improvement immediately after treatment Follow-up later revealed im- provement
16 38 M	Chronic diffuse pneumo- nitis	10	100,000 units of aerosolized penicillin dissolved in physiologic saline solution every 24 hr	5 mo.	Beta-hemolytic streptococcus, non- hemolytic <i>Staph aureus</i> pre- dominantly	Patient seen in October, 1946, and was un- improved
17 44 M	Chronic sinusitis with bronchial asthma	10	100,000 units of aerosolized penicillin dissolved in physiologic saline solution every 24 hr	Since childhood	Alpha-hemolytic streptococcus and <i>M. albicans</i> hemolytic <i>Staph aureus</i> beta-hemolytic strepto- coccus and <i>Esch coli</i>	Marked improvement. Patient recently had upper respiratory cold, but no recurrence of the asthma
18 67 M	Bronchiectasis	10	100,000 units of aerosolized penicillin dissolved in physiologic saline solution every 24 hr	10 yr	<i>Staph albus</i> beta-hemolytic strep- tococcus predominantly heavy growth of <i>Esch coli</i> negative for gram positive cocci	Patient made good improvement. His breath- ing was greatly helped by reducing infection and increasing vital capacity
19 43 F	Bronchiectasis ques- tionable Boeck sarcold	10	100,000 units of aerosolized penicillin dissolved in physiologic saline solution every 24 hr	2 yr	Alpha-hemolytic streptococcus	Patient has improved, but has changed resi- dence from New York to Arizona which may be responsible for continued improvement
20 19 M	Bronchiectasis with chronic sinusitis	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 24 hr	15 yr	Nonhemolytic <i>Staph albus</i> and <i>Staph aureus</i> predominantly streptococcus	Patient showed immediate improvement but later had recurrence (one year) Recent attempts to follow up of no avail

TABLE 2 (Continued)

CASE No.	AGE	SEX	DIAGNOSIS	DURATION OF TREATMENT	TREATMENT	DURATION OF ILLNESS	ORGANISMS RECOVERED	COMMENT
21	45	M	Chronic bronchiectasis with anastomotic attacks	46	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 24 hr	1 mo.	<i>E. coli</i>	Patient made immediate improvement. Recurrent follow-up cannot be obtained.
22	59	F	Chronic bronchiectasis with anastomotic attacks	7	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 24 hr	1 yr	Fungi resembling <i>M. abscessus</i> ; nonhemolytic streptococcus predominantly (same as type)	Slight temporary improvement immediately after hospital discharge. No permanent improvement.
23	44	M	Chronic bronchiectasis with anastomotic attacks	14	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 24 hr	14 yr	Alpha hemolytic streptococcus predominantly; few colonies of nonhemolytic streptococcus; few colonies of alpha hemolytic <i>Staph. aureus</i> ; <i>B. subtilis</i> <i>M. abscessus</i>	Patient made immediate improvement. Recurrent follow-up cannot be obtained.
24	51	M	Chronic sinusitis, with diffuse bilateral bronchiectasis	10	100,000 units of aerosolized penicillin dissolved in physiologic saline solution every 24 hr	29 yr	Predominantly <i>Staph. aureus</i> ; hemolytic and nonhemolytic streptococcus	Moderate improvement, but follow-up showed need for supplementary treatment, now This patient a physician
25	45	F	Chronic paranasal sinusitis	10	200,000 units of aerosolized penicillin dissolved in physiologic saline solution every 8 hr	6 mo.	Alpha-hemolytic streptococcus predominantly; also colonies of hemolytic <i>Staph. aureus</i> and several colonies of <i>E. coli</i>	Follow-up one year after treatment indicates good improvement maintained
26	72	M	Chronic bronchiectasis	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	Since childhood	Hemolytic streptococcus; <i>Staph. aureus</i> predominantly	Result unsatisfactory, probably owing to diffuse paranasal sinusitis with clamps as result of submergent accident in childhood
27	57	M	Chronic sinusitis	10	100,000 units of aerosolized penicillin dissolved in physiologic saline solution every 12 hr	14 yr	<i>Staph. aureus</i> predominantly; <i>Staph. aureus</i> long in sinus drainage; <i>Staph. aureus</i> predominant in axillary abscesses; alpha hemolytic and nonhemolytic streptococcus; some beta hemolytic streptococcus	Immediate improvement but follow-up showed some recurrence overall benefit derived however
28	51	F	Chronic bronchitis, with recurrent attacks	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	10 yr	Nonhemolytic streptococcus; some <i>Staph. aureus</i> and <i>E. coli</i>	Patient has not benefited by therapy; in fact she considers herself more susceptible to cold since treatment.
29	22	M	Cold and productive cough	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	1 1/2 yr	<i>E. coli</i> only predominantly; few nonhemolytic streptococci and <i>Staph. aureus</i>	Result excellent until patient contracted cold, when she disappeared, however
30	67	M	Chronic bronchiectasis	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	3 yr	<i>Staph. aureus</i> found resembling <i>M. abscessus</i> ; beta hemolytic streptococcus predominantly	Temporary improvement; report in December, 1946, indicated improvement not permanent.
31	45	M	Chronic bronchiectasis with chronic sinusitis	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	1 1/2 yr	<i>Staph. aureus</i> predominantly; some alpha hemolytic and beta hemolytic streptococcus	Good result; patient states that there is great improvement with little or no expectation
32	37	M	Chronic bronchitis, with chronic sinusitis	10	100,000 units of aerosolized penicillin dissolved in physiologic saline solution every 12 hr	15 yr	Nonhemolytic streptococcus and <i>Staph. aureus</i>	Good result; patient originally referred for treatment of sinusitis; we did not endeavor plan and penicillin by nasal route helped recovery
33	60	M	Chronic bronchitis with chronic sinusitis and diabetes	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	4 yr	<i>Staph. aureus</i> in sinus drainage; beta hemolytic streptococcus and some nonhemolytic streptococci	Moderate improvement maintained since April 1946
34	57	F	Chronic bronchitis	10	60,000 units of aerosolized penicillin dissolved in physiologic saline solution every 12 hr	6 mo.	Few nonhemolytic streptococci; hemolytic <i>Staph. aureus</i> predominantly	Patient made excellent improvement and states that she now has no expectoration
35	44	M	Bronchiectasis, with severe emphysema of lung	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	15 yr	Hemolytic <i>Staph. aureus</i> ; <i>Staph. aureus</i> ; <i>Staph. aureus</i> ; <i>Staph. aureus</i> ; <i>Staph. aureus</i>	Very satisfactory result; patient has had no hemorrhages and a minimum of expectoration
36	66	M	Chronic bronchitis	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	25 yr	Alpha hemolytic streptococcus predominantly; nonhemolytic streptococcus	Moderate improvement, but result not entirely satisfactory
37	42	F	Bronchiectasis, with massive hemorrhage of lung	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	10 yr	Nonhemolytic streptococcus	Excellent improvement which has been maintained since October 1946
38	60	F	Bronchiectasis, with hemoptysis	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	40 yr	<i>Staph. aureus</i> ; nonhemolytic streptococcus	After many years of treatment elsewhere patient made remarkable recovery with penicillin made remarkable recovery with penicillin by nasal route
39	45	F	Acute exacerbation of chronic sinusitis	10	100,000 units of aerosolized penicillin dissolved in Zephiran chloride every 8 hr	3 yr	Nonhemolytic <i>Staph. aureus</i>	Very satisfactory result obtained with penicillin by nasal route

Supplementary parenteral treatment was given in each case as described above

therapy and to a reconsideration of the topical treatment of infection, both with benefit to the patient. All material accumulated over a period of two and a half years is reported. Follow-up reports have been established in all these cases.

METHOD

Our original technic was to give the patient 50,000 units intramuscularly on admission to the hospital and to follow this with 10,000 every three hours for ten days. In many cases, to avoid unnecessary injections, we gave 50,000 units every twelve hours in Pendil for the required ten days. Intramuscular penicillin serves to supplement penicillin aerosol. Recently, to diminish the discomfort of frequent intramuscular injections, we have been giving 300,000 units of penicillin in 1 cc of beeswax and peanut oil every twenty-four hours, since Romansky and Rittman³⁹ have demonstrated that an assayable blood level may thus be maintained for about one day. In subsequent discussions of the value of aerosol therapy, the possible therapeutic contributions of parenterally administered antibiotics are implied.

In preparation for aerosol therapy we now use 0.5 cc of a 0.25 per cent solution of Neo-Synephrine in the nebulizer. This the patient deeply inhales before starting the treatment with penicillin. Neo-Synephrine is immediately followed by deep inhalation of 100,000 units of penicillin dissolved in 3 cc of Zephiran in a 1:1000 aqueous solution every eight hours. The patient is carefully instructed concerning the basic anatomic and physiologic principles involved so that he will use forced expiration and then deeply inhale to the full limit of his vital capacity, simultaneously breathing in the aerosolized penicillin with the detergent. Emphasis on this important phase of the therapy is vital if the topical principle is to be fully exploited. The patient is instructed to prolong inhalation one or two hours by resting between each inhalation. When finished, to utilize more fully the penicillin that is retained on the walls of the glass nebulizer, 1 cc of physiologic saline solution introduced into the same nebulizer is inhaled. This procedure is followed every eight hours for ten days. All patients have been hospitalized during the interval of treatment. In the hospital we were able to obtain the necessary bacterial cultures and to correct minor difficulties in technic. From the onset we were desirous of maintaining an adequate dosage of penicillin for a prolonged period so that the artificial selection of penicillin-resistant organisms, as described by Rammelkamp and Maxon,⁴⁰ could be avoided. In 4 cases, urticarial swelling and itching followed the administration of penicillin by inhalation.

TREATMENT OF CHRONIC SINUSITIS, TRACHEOBRONCHITIS AND BRONCHIECTASIS

Chronic tracheobronchitis, often associated with bronchiectasis, pulmonary emphysema and sinusitis,

has been the most frequent type of respiratory infection for which we have found penicillin aerosol to be of aid. The sulfonamides have been administered in aerosol form in the treatment of bronchiectasis by Stacey.⁴¹ Olsen¹⁰ has given penicillin aerosol to 7 patients hospitalized for pulmonary resection, stating that the method is the best available to prevent complications following complete or partial lobectomy for pulmonary suppurative disease. Among 8 cases of bilateral or inoperable bronchiectasis, Olsen reports immediate improvement in 7 with thinning and reduction of sputum, but with some later remissions. Segal and Ryder¹³ suggest that periodic retreatment with aerosols may be necessary in the proper management of inoperable bronchiectasis. Barach¹¹ states that no improvement occurred in 3 of 7 cases of bronchiectasis associated with other bronchial or pulmonary infection, and of 4 improved patients remission was later evident in 2. Barach administered 100,000 to 200,000 units of penicillin as aerosol over a period of five to thirty-five days. Bobrowitz et al.⁴² have also noted a tendency for remission to occur after treatment of bronchiectasis with intramuscular injections, intratracheal instillation and aerosolization of penicillin. The complete fibrotic reorganization and irreversible functional damage resulting from chronic bronchiectasis and bronchiolectasis make it probable that repeated bacterial infection follows the most thorough and effective therapeutic program. In the evaluation of improvement, allowance must be made for the usual seasonal fluctuations in cough, and no amelioration may be regarded as permanent without prolonged and possibly lifelong observation.

A chronic syndrome of sinusitis associated with either bronchitis or bronchiectasis is frequent (Table 2). Upper respiratory infection has been treated as a general problem with aerosolized and supplementary intramuscular penicillin. More recently, Zephiran in a 1:1000 solution has been used as a solvent for penicillin, to be given as an aerosol. The resulting turbid suspension forms a stable mist.

Among 21 patients with bronchiectasis treated by penicillin aerosol therapy, adequate subsequent observations extending up to two years have been obtained. Of these, 5 were not helped, 6 improved temporarily but relapsed, and 10 were definitely benefited. A possible contribution to improvement was temporary hemidiaphragmatic paralysis produced by crushing of the phrenic nerve in 2 of the improved patients, both of whom had experienced hemorrhage and hemoptysis. In the group with bronchitis, 1 patient was not relieved, 1 relapsed after temporary disappearance of symptoms, and 8 showed improvement. In addition, a patient with bronchitis was aided, but in this case the observation period since treatment extended only for two months. Aerosol treatment of sinusitis may be quite effective, and suitable instruments with affixed

nasal catheters may now be obtained * Sixteen persons with sinusitis either singly or in combination with other respiratory ailments received penicillin in physiologic saline solution or Zephiran as an aerosol Recent histories are available for 13 patients, of whom 10 showed clinical improvement with no relapse

DIFFUSE PULMONARY FIBROSIS WITH LIMITED VITAL CAPACITY

Pneumoconiosis caused by prolonged exposure to silicon dust and characterized by nodular fibrosis and emphysema has been recognized as an occupational disease for many years⁴ Even when the proportion of inhaled silicon dioxide is relatively lower, as in certain coal-mining activities, a diffuse perilymphatic fibrosis is often associated with anthracosis The resultant dyspnea may be a severe physical handicap

It is now realized that the proper control of occupational pneumoconiosis should be prophylactic Yet persons engaged in mining activities before adequate protection had been made to prevent irreversible fibrotic damage to the lung present a serious and tragic problem Any therapeutic agent that will help this group with reduced vital capacity demands consideration by physicians engaged in industrial medicine Treatment with penicillin aerosol has been found to be of definite benefit in decreasing the respiratory deficiency noted in diffuse pulmonary fibrosis of occupational origin The following brief abstracts of case reports are of interest.

CASE 40 A 68-year-old man with extensive fibrosis of both lungs had worked for many years in a granite quarry any activity produced marked dyspnea Examination disclosed many rales in the chest Aerosolized penicillin was given in October, 1944 producing great relief from the dyspnea A cerebral accident, with hemiplegia recently occurred and the patient is now in a county hospital. Dyspnea presents no problem at present.

CASE 41 A 56-year-old man who had been a coal miner most of his life had considerable dyspnea in April 1945, with limited activities as a doorman Aerosolized penicillin was given in April, 1945 and the patient has carried on all his duties with no discomfort At present he has been urged to return for a yearly repetition of treatment but refuses because he has no symptoms and feels in good health

Since the vital capacity lost as a result of pulmonary fibrosis cannot be replaced, the cause of clinical improvement subsequent to the use of penicillin aerosol in pneumoconiosis is obscure The marked and unexpected regression in symptoms of dyspnea may have been due to a reduction in associated infection, with a resultant increase in vital capacity By all clinical signs, both patients have been greatly helped Physicians in mining areas confronted with the problem of silicosis and anthracosis are urged to investigate and report on a larger series of such

cases in which penicillin aerosol has been used The cases discussed above are insufficient to permit any categorical conclusions

SEVERE ASTHMA

The treatment of infective intrinsic asthma by penicillin aerosols has been reported by Barach¹¹ and by Segal and Ryder¹² Barach summarizes the result of his favorable experience, stating that of 4 patients relieved of asthmatic symptoms for one or two months but with subsequent remission, 2 were successfully treated by a second course of aerosol therapy Since most asthma is extrinsic in origin it is essential that a careful diagnosis be made to determine the etiologic role of bacteria before a program of penicillin aerosols is begun

Segal and Ryder¹² described no marked change in bronchospasm following penicillin aerosol therapy administered to 6 asthmatic patients The excellent result obtained in the following case may have depended in part on the use of a germicidal detergent (Zephiran in a 1:1000 aqueous solution) as a solvent for the penicillin

CASE 42 A 16-year-old boy with a history of severe infective intrinsic asthma for 8 years, which had been getting progressively worse, could not play or move about with companions At present, 18 months after the administration of aerosolized penicillin he has had only one attack and is able to carry on all normal activities for his age with no discomfort In November, 1946, he was seized with an upper respiratory infection and 48 hours later he had an asthmatic attack He was immediately hospitalized and aerosol therapy instituted with penicillin and streptomycin each for five days The patient responded satisfactorily and now has no symptoms.

Prevailing opinions on the value of asthma penicillin aerosols in the treatment of asthma are contradictory and will presumably remain so, in view of the complex physiologic nature of the disease Asthma should properly be considered a symptomatic response to a wide variety of conditions, including allergic, toxic and psychogenic factors therefore, it does not appear probable that treatment of associated infection will always be successful Yet, in our opinion, and that of Barach,¹¹ aerosol therapy may be a satisfactory method of treatment if justified by bacteriologic studies

PUTRID LUNG ABSCESS

In 1942 Maier and Grace¹³ reported the distinct clinical entity of putrid empyema, recommending treatment through surgical drainage by open thoracotomy Confirmation was afforded the previous observation of Neuhof and Hirshfeld¹⁴ on the anaerobic nature of the causative micro-organisms Infection with anaerobic streptococci and staphylococci, mixed with spirochetes and aerophilic bacteria, has been described not only in putrid empyema but also in putrid lung abscess Since putrid empyema develops most frequently from the intrapleural rup-

*DeVilbiss 640 obtainable from DeVilbiss Company 111 E 54th Avenue New York City

ture of bronchiectatic or abscessed regions of the lung, particular interest is attached to the adequate control of these contributory diseases. The aim of medicine should be preventive rather than remedial.

In the following case, aerosolized penicillin in Zephiran, supplemented by parenteral penicillin, was successful in curing a putrid lung abscess without surgical interference.

CASE 43 This patient gave a history of so-called "pneumonia" for 3 weeks, which had been getting progressively worse, with expectoration of $\frac{1}{2}$ to 1 cupful of foul, putrid sputum a day and a daily temperature of 103°F. X-ray study showed a large lung abscess in the right upper lobe. Penicillin was given parenterally, with penicillin in Zephiran aerosol (for 10 days), and the patient promptly made an uneventful recovery. At follow-up study 3 months later, there were no symptoms. X-ray examination showed complete resolution of the abscess.

The topical administration of penicillin-detergent solutions may ultimately prove to be of aid in the elimination of gram-negative bacilli and penicillinase-producing bacteria symbiotically involved in putrid lung abscess and ordinarily unchecked by penicillin alone. It is essential that a detergent capable of acting in high dilution, whose antibacterial properties have been studied, be utilized. At the same time, a conservative distinction must be drawn between the accepted germicidal potentialities of detergents in vitro and their largely undetermined value as inhalational aerosols. Without undue optimism it is believed that the prompt and judicious use of aerosol therapy will, on occasion, prevent the desperate clinical picture of advanced anaerobic infection. When surgery is indicated for pulmonary disease, preoperative treatment with aerosols should be of value, according to the principles elaborated by Olsen.¹⁰

ACTIVE PULMONARY TUBERCULOSIS

Since the tubercle bacillus is not sensitive to penicillin concentrations ordinarily attainable, it is at once evident that penicillin aerosol does not afford the promise of streptomycin in the treatment of tuberculosis. It is well known, however, that a considerable degree of damage in tuberculosis of the lungs is caused by associated bacteria, notably staphylococci and streptococci. If these secondary invaders could be controlled by penicillin, it was thought that a possible resultant reduction in bacterial flora and general toxemia might provide an opportunity for the natural defenses of the body to effect an arrest or regression of the disease.

The following are brief abstracts of cases treated for secondary infection with penicillin aerosol.

CASE 44 This 26-year-old patient had pulmonary tuberculosis of the left upper lobe, with multiple cavities, positive sputum and a high sedimentation rate (77 mm in 1 hour by the Westergren method). The phrenic nerve was crushed, and hemidiaphragmatic paralysis was done, with aerosol therapy as described above. The patient was not helped.

CASE 45 This 34-year-old patient gave a history of tuberculosis of the right upper lobe of 10 years' duration. The

sputum was positive. Frequent rest and artificial pneumothorax had been unsatisfactory, aerosolized penicillin was not helpful, but was regarded as an important preoperative aid to a two-stage thoracoplasty. The sputum was negative for a period, and the patient actively engaged in business. The treatment was perhaps instrumental in changing a case of acute pulmonary tuberculosis to a chronic one by control of the secondary infection in the lung and diminishing of systemic toxemia. A preliminary phrenic-nerve operation had been done. The possibility that temporary improvement would have occurred spontaneously without treatment cannot be ruled out. Four months after discontinuation of treatment a positive sputum and evidence of activity in the lung were found.

CASE 46 This 44-year-old patient had bilateral pulmonary tuberculosis, with cavitation in the left lung. The sputum was positive, and the sedimentation rate was high. Aerosolized penicillin was not helpful.

CASE 47 A 40-year-old woman had extensive bilateral pulmonary tuberculosis. There was a high sedimentation rate (78 mm in 1 hour). The sputum was positive. Aerosolized penicillin was used, but the vital capacity was so limited that the patient could not follow the prescribed technique of deep inhalation. This patient died four months later from pulmonary tuberculosis. The use of aerosolized penicillin was unsatisfactory.

These 4 patients with advanced tuberculosis were treated before streptomycin became available and were not benefited by efforts to control secondary bacterial invaders with aerosolized penicillin.

Streptomycin as an aerosol has been employed by Nichols and Herrell⁴⁶ and by Olsen⁴⁷ in the treatment of bronchiectasis with gram-negative involvement, and also by Hinshaw, Feldman and Pfuetz⁴⁸ in the therapy of tuberculosis. It is perhaps significant that streptomycin has been reported to be less diffusible in the body than penicillin—an observation indicating possible advantages in the topical treatment attainable by aerosolization. The use of streptomycin as an aerosol in the treatment of pulmonary tuberculosis appears, a priori, to be worthy of extensive investigation. We have had the opportunity to hear both Hinshaw and McDermott report their experiences in the therapy of tuberculosis with parenteral streptomycin. Since streptomycin as now administered appears in some cases to be merely a palliative,⁴⁸ a co-ordinated therapeutic program may be required, involving suppression of the tubercle bacillus and any secondary infection, together with adequate diet and rest for the patient. Efforts to increase liver efficiency may do a great deal to diminish damage by bacterial toxins. By aerosol therapy it may be possible to deliver streptomycin topically and in larger doses than can be placed in the lung by parenteral methods. One of us (E. J. G.) believes that thoracoplasty should not be done until the more conservative plan of therapy has been adequately tried. With a larger output of streptomycin gradually becoming available, a method of topically placing this antibiotic or other chemotherapeutic agents in more direct contact with tuberculous lesions in the lung might have a profound effect in limiting the magnitude of thoracic surgery required in the treatment of pulmonary tuberculosis and in altering the course of the disease.

In addition to the administration of aerosolized penicillin in Cases 44-47, a small series of patients were treated with streptomycin aerosol, the detergent Zephiran in a 1:1000 aqueous solution being used as a solvent. In the topical eradication of acid-fast bacteria isolated in fibrosed, calcified or caseous tubercles the potential significance of an acutely germicidal and detergent aerosol becomes obvious. Yet we do not at present know if the necessary level of germicidal and detergent efficiency can be reached without associated toxic and hemolytic effects. Our present clinical experience is too inadequate to justify report of more than the arrest of pulmonary tuberculosis with symptomatic improvements in 4 patients treated with streptomycin in Zephiran, 1 of whom (Case 49) received direct intrapleural instillation for bronchopleural fistula.

CASE 48. This 36-year-old patient stated that in 1934 a diagnosis of left pulmonary tuberculosis had been made. Artificial pneumothorax was given until 1938 when pleural fluid was aspirated and *Mycobacterium tuberculosis* was found. Subsequently the patient developed a chronic tuberculous empyema that had drained constantly for 8 years and entered the Grace Clinic in 1941. All accepted methods of treatment, including complete thoracoplasty of the left side were used but empyema continued to drain. Biopsy of the visceral and parietal pleura showed a classic picture of tuberculosis. On October 14 and 15, 1946, a solution was made of 20 cc. of Zephiran chloride aqueous solution (1:1000) with 1 gm. of streptomycin and 5 cc. was injected directly into the pleural cavity every 5 hours for six doses. Five days later the chronic tuberculous sinus tract closed for the first time in 8 years and now, 1 year later, it is still closed. The clinical condition is now good.

CASE 49. A diagnosis of pulmonary tuberculosis in this 37-year-old woman was made in 1929. A continuous artificial pneumothorax was given. The patient, when 2 months pregnant, developed a bronchopleural fistula with a fluid level 9 cm. above the left leaf of the diaphragm. Empyema fluid drained into the fistula. There was a continuous cough. The patient spoke with difficulty. She appeared moribund when seen on November 14, 1946. The immediate problem was supportive treatment with control of the empyema and bronchopleural fistula of the left side. For the following 7 days 1 gm. of streptomycin dissolved in 10 cc. of 1:1000 aqueous solution of Zephiran was injected into the pleural space and 200,000 units of streptomycin and 100,000 units of penicillin were administered intramuscularly every 12 hours in beef wax and peanut oil for 6 weeks. The patient gave birth prematurely on November 22, 1946. The baby died. The hacking cough and copious expectoration started to subside after the intrapleural instillation of streptomycin detergent and have now been eliminated. The fluid level was reduced to 3.7 cm. All clinical and laboratory data confirm the obvious symptomatic improvement. The seriousness of the illness may be gauged by the fact that the patient cannot recall anything that took place during the first ten days of her confinement to the hospital. Aerosolized penicillin therapy was attempted and stopped because of great distress to the patient, with some hemoptysis. The possibility of mediastinal shifting and flitter with consequent circulatory and respiratory embarrassment may preclude forced breathing of aerosols when bronchopleural fistula is present.

CASE 50. A 29-year-old patient was known to have had bilateral tuberculosis for 3 years. She entered the Grace Clinic on November 13, 1946 with a hydropneumothorax of the right side. Diffuse mottling and infiltration were noted throughout the left portion of the chest. On the right a temporary hemidiaphragmatic paralysis was accomplished by crushing of the right phrenic nerve. On December 20 the patient was given 100,000 units of penicillin and 200,000 units of streptomycin as aerosol in 3 cc. of a 1:1000 solution of Zephiran every 8 hours together with 200,000 units of streptomycin in beef wax and peanut oil every 12 hours.

Penicillin streptomycin-detergent aerosol was continued for 3 weeks. Streptomycin given intramuscularly has been continued to date.

CASE 51. A 28-year-old woman had been seen at various intervals since March 7, 1945. She had no specific complaint except slight colds, with a minimal cough at various times, and fatigue. X-ray studies of the chest on six occasions from the first visit failed to establish any definite diagnosis. On October 30, 1946 the patient had an acute cold and cough. Routine x-ray study of the chest on that date was reported as showing a moderate lobular lesion involving the left apex. In the first interspace anteriorly there was a small cavity in this apical lesion. The patient was hospitalized immediately, and antibiotic therapy started. Penicillin and streptomycin were given with detergent Zephiran Chloride in a 1:1000 solution as an aerosol and also systemically in peanut oil. X-ray studies on January 2, 1947 revealed moderate fibrosis to the left apex. The cavity was no longer visible. There was no definite evidence of active infiltration at that time. The patient could take aerosolized streptomycin and penicillin for only 1 month but from the onset of therapy she had had 0.5 gm. of streptomycin daily. Treatment was begun on November 1, 1946, and is being continued to date. This patient has clinically made a satisfactory recovery as confirmed by x-ray examination, but in spite of the clinical improvement a high sedimentation rate (38 mm in 1 hour by the Westergren method) indicates the importance of not permitting clinical or x-ray data alone to determine the plan of a patient's activity.

Any attempt at present to judge the merit of the therapeutic programs outlined would be premature. Yet there can be no doubt that symptomatic improvement has occurred, and it is highly probable that death was imminent in Case 49 before treatment was instituted. Complete laboratory reports have been kept, and include findings of negative sputum after treatment. As a negative finding, however, the absence of *Mycobacterium tuberculosis* in the sputum is regarded as of doubtful diagnostic value. No vestibular disturbances have been reported by the patients. Although not properly within the scope of a paper on aerosols, Cases 48 and 49 have been included as examples of the local employment of antibiotic-detergent therapy, which assumes significance in the light of Hineshaw's findings. Hineshaw et al.¹⁴ state that among 7 cases of tuberculous empyema treated with streptomycin routinely, definite improvement was noted in only 1. The refractory nature of tuberculous empyema is ascribed in part by these investigators to the granulomatous nature of the diseased pleura. The reduced surface tension of streptomycin detergent may afford a more efficient infiltration of superficial granulomatous processes.

One of us (E. J. G.) has had the opportunity to participate in surgical treatment of pulmonary tuberculosis during the last two decades, in county hospitals, private sanatoriums and private practice. During that period the radical surgical procedures advocated above have been employed. In the late follow-up study of patients treated by radical surgery it is tragically evident that surgical procedures are often far from ideal. It is now generally agreed that the accepted conservative procedure of bed rest, adequate diet and nursing care remains the method of choice in the treatment of tuberculosis. Anti-

biotic-detergent aerosol therapy should be regarded as a supplement to the conservative management of tuberculosis, an approach that should be thoroughly explored before resorting to surgery. Since others have reported the arrest of pulmonary tuberculosis with parenteral streptomycin,⁴⁸ any proper evaluation of topical streptomycin-detergent therapy must await the accumulated experience of careful observation over a long period.

SUMMARY

The mechanical equipment necessary for effective aerosol therapy is preferably simple, consisting of a suitable nebulizer for oral inhalation and a nebulizer with attached cannulae for nasal inhalation. The distinction between atomizers and nebulizers should be understood by the physician. The medical use of aerosols demands a basic knowledge of the fundamental physical principles involved in the behavior of inspired particles of different sizes.

Aerosol therapy is considered a form of topical treatment. Topical administration of antibiotics in detergent solutions may provide the physical advantages associated with reduced surface tension and the antibacterial advantages contingent on synergism and the reduced likelihood of drug-fast infection.

Clinical experience of more than two years has shown antibiotic aerosol therapy to be a valuable supplement to parenteral treatment of respiratory disease, including intrinsic infectious asthma, bronchitis, bronchiectasis, sinusitis and, more recently, tuberculosis. Except in selected cases, aerosol therapy should be attempted before surgery is resorted to.

SERVICES OFFERED TO THE PHYSICIAN BY THE MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH*

VLADO A. GETTING, M.D.†

BOSTON

IN 1850 Lemuel Shattuck, a representative in the General Court of Massachusetts and a bookseller in Concord, alarmed to find that so many persons died in the prime of life, presented the first sanitary survey, entitled "Report of a General Plan for the Promotion of Public and Personal Health," to the General Court. In 1869 the first state board of health in the country was established by the General Court in Massachusetts. This Board was authorized to take cognizance of the interest of health and life among the citizens of Massachusetts, and to make sanitary investigations and inquiries concerning the people, the causes of disease, especially of epidemics, the sources of mortality and the effects of localities, employments, conditions and circumstances on the public health, as well as to gather information regarding such matters as it may deem proper for diffusion among the people. In subsequent legislation, the Massachusetts Department of Public Health was given broad authority, which has continued to increase, and is now charged with the following responsibilities: to make investigations of the sale of drugs and food and adulterations thereof, to advise the government and others of sanitary conditions in public institutions, to have oversight of inland waters and sources of water supply, as well as vaccine institutions, and to produce and distribute antitoxin and vaccine lymph and such specific serums for protective inoculations, diagnosis or treatment against typhoid fever and other diseases as the Department may from time to time deem advisable, to make annual examinations of all main outlets of sewers and drainage of the towns of the Commonwealth, to define diseases dangerous to the public health, to investigate contagious diseases, to furnish remedies for ophthalmia neonatorum, and to make minimum isolation and quarantine regulations. Many other responsibilities too long to list in this presentation have been assigned to the Department of Health.

Passing through many vicissitudes of organization, the Board of Health eventually assumed its present form in 1914 as a department of public health with an advisory public-health council and a commissioner as the administrative executive officer. It now employs approximately eighteen hundred people and expends an annual budget of about \$8,000,000 derived from state, federal and private funds. The Department of Public Health has be-

come responsible not only for the preventive aspects of public health but also for the promotion of optimal health and for the administration of medical-care programs, it is also charged with the direction of five state institutions.

ORGANIZATION

The Commissioner, appointed for a period of five years by the Governor, is charged with the administration of the laws relative to health and sanitation and the regulations of the Department. He is required by law to prepare rules and regulations for the consideration of the Public Health Council and to direct employees of the Department to assist in the study, suppression or prevention of diseases in any part of the Commonwealth. Annually, he must submit to the Council a report containing recommendations regarding health legislation. He is required to be a physician schooled in sanitary science and experienced in public-health administration. He is the executive and administrative head of the Department and acts *ex officio* as chairman of the Public Health Council.

The Public Health Council, consisting of the Commissioner and six other members, meets at least once a month. Members are appointed by the Governor, one each year for a term of six years. The Council is required to promulgate rules and regulations, take evidence in appeals, hold hearings and discharge its duties as required by law. Hearings may be held by the Commissioner or by a director of a division of the Department if so authorized by the Commissioner and Council.

Divisional Organization

Because of the complex field activities, the Department is divided into the following sections: Administration, Biologic Laboratories, Cancer and Other Chronic Diseases, Communicable Diseases, Dental Health, Food and Drugs, Local Health Administration, Maternal and Child Health, Sanitary Engineering, Tuberculosis and Venereal Diseases.

Administration. This division, whose director is the Commissioner, is concerned primarily with the over-all administration of the Department, including physical and personnel matters, the development of rules and regulations, state and federal legislation, the dissemination of information through the Bureau of Health Information, the licensing of hospitals and the conduct of the Hospital and Health Center Survey and Plan, as authorized by Public Law 725, whereby Massachusetts is to receive a sum

*Presented at the annual meeting of the Massachusetts Medical Society May 22, 1947.

†Commissioner, Massachusetts Department of Public Health.

of \$8,000,000 over a period of five years, provided it be matched by double this amount in local or state funds, for assistance in the construction of health centers and hospitals, which are included in a plan now being developed under the direction of a special commission appointed by the Governor. A survey of hospitals and public-health centers is being completed to determine the actual needs of the Commonwealth, and the formulated plan is to provide coverage to meet existing needs.

Through the efforts of the Bureau of Hospital Licensing, improvements have been made in hospital staff organization, hospital records, obstetric care and the management of nurseries for the newborn. The Division of Administration advises local boards of health, voluntary health associations and professional organizations and consults them regarding the administration of the Department. It acts as a co-ordinating or liaison group with other governmental departments. The Commissioner serves as a member of the Milk Regulation Board and the Rating Board, and, most important, he also serves as a member of the Massachusetts Approving Authority for Medical Schools. This last organization has been effective in raising the standards for medical practice in Massachusetts. The Department of Public Health receives advice and federal grants-in-aid from the United States Public Health Service and the Children's Bureau, both in the Federal Security Agency. These funds are received for the following purposes from the Public Health Service for venereal-disease control, tuberculosis control, general public health, industrial hygiene, cancer, hospital construction and survey, and from the Children's Bureau for maternal and child health, crippled-children's services and emergency maternal and infant care. Private funds are also expended for various specifically designated purposes.

Dental Health This is the newest division of the Department and is primarily concerned with the promotion of dental-health education, the development of programs for the prevention of dental caries, the promotion of dental clinics for children and the dissemination of information relative to the care of teeth of children and adults. At present the Department is not conducting any service program except through well-child conference demonstrations in which dentists and dental hygienists make examinations and inspections of teeth for the information of parents, referring the children to the family dentists for treatment.

Food and Drugs This division is truly the policeman of the Department and is primarily concerned with the sanitation and safety of foods and, secondly, with the purity of contents and the consumer value of foods and drugs. Inspections are made of all types of food-manufacturing establishments, including bakeries, slaughtering houses, poultry-slaughtering houses, pasteurization and other milk-handling concerns, wholesale and retail stores, cold-storage

plants, soft-drink manufacturers and other food-processing establishments and restaurants. In addition, samples of many foods and drugs, as well as filling material of mattresses and upholstered furniture, are collected for analysis for adulteration, misbranding or safety. This assures the consumer that he is buying what he thinks he is buying, and that the food that he consumes is not only nutritious but also safe and sanitary. Through the Division of Food and Drugs licenses are issued to manufacturers and wholesale distributors of narcotic drugs. Routine check-up examinations are made on pharmaceutical products, especially those liable to deterioration (such as vitamin B₁ and digitalis), and on the accuracy of druggists in filling prescriptions. Notification to physicians is made of products determined harmful or dangerous to use.

Maternal and Child Health This division is responsible for the promotion of prenatal care, for the development of a program for the care of premature infants, for the institution of refresher courses for physicians, for the conduct of well-child conferences and for the promotion of both preschool and school health programs. It has developed the Massachusetts vision test, which has replaced the Snellen chart, and is now promoting audiometer testing of the hearing of the children. Audiometer testing is done in groups and checked on an individual basis. Children who have apparent visual or hearing defects are referred to physicians for follow-up study. This division is also responsible for the administration of the Crippled Children Services — a program that has been co-ordinated with the activities of the District Medical Societies. Consultants for the state clinics are available together with a corps of other specialists, such as physical therapists, nurses, medical social workers and nutritionists, to assist in the care of children who are referred by physicians or social agencies. Any child may obtain diagnostic services, but only children whose families cannot afford to pay for medical and hospital care are accepted for treatment. One of the war activities has been the Emergency Maternity and Infant Care Program, which is in the process of gradual liquidation. Under this program any woman who was eligible prior to June 30, 1947, may receive benefits for maternity care. This includes the payment of physicians in accordance with the fee schedules set up by the Children's Bureau, and hospital services in accordance with schedules for payment to hospitals on a cost basis. The number of maternal cases cared for under this program as of May 1, 1947, was 32,643, including 15,668 from September, 1943, to December 31, 1944, 10,072 in 1945, 6284 in 1946, and 619 from January 1 to May 1, 1947. Servicemen's children under one year of age are eligible for health supervision and pediatric care on a similar schedule of fees to physicians and a payment based on cost to hospitals. The total number of children as of May 1, 1947, was 9255, including 2521

from September, 1943, to December 31, 1944, 3117 in 1945, 2833 in 1946, and 784 from January 1 to May 1, 1947. The Division is particularly concerned with the development of a school health program in co-operation with the Department of Education and, it is hoped, the inauguration of a local school-physician consultant service for this purpose.

Sanitary Engineering One of the largest divisions of the Department is that of Sanitary Engineering, which is responsible for the supervision of water supplies, sewage disposal and drainage systems and for advice to cities, towns and persons on water supply and sewerage problems. All construction or reconstruction of these plants must be approved by the Department. An extensive laboratory for chemical and microscopical analysis of specimens of water and effluents of sewage-disposal systems is located in the State House and also at the Lawrence Experiment Station, where a bacteriologic laboratory is also maintained and where many systems now used throughout the country for the treatment of water, industrial wastes and domestic sewage have been developed.

This division is also responsible for the abatement of noisome trades, — that is, industries that may cause a nuisance because of odors, — for the control of pollution of streams, ponds and tidal waters, for the supervision and approval of areas for the taking of shellfish and for the operation of shellfish-purification plants and shellfish-handling establishments. This division is also responsible for the general over-all supervision of cross-connection between plumbing and sewage-disposal systems.

Biologic Laboratories The Division of Biologic Laboratories has more than doubled in size in the past two years. Its primary function has been the manufacture of prophylactic and therapeutic biologic products. The Massachusetts Department of Health was the first to make diphtheria antitoxin available for the treatment of diphtheria. We are now adding to our present products the manufacture of whooping-cough vaccine and hope to add tetanus toxoid in the near future. It is the Department's recommendation that every child three months to six months of age should be immunized against whooping cough, and those six months to nine months against diphtheria, and that whenever possible, tetanus toxoid be added in whatever combination with the above two that the physician may desire. The Department expects to manufacture all three products in various combinations for free distribution as soon as personnel becomes available. In addition, the child at about nine months should be vaccinated against smallpox. Ideally, if the family can afford the expense, a booster inoculation of whooping-cough vaccine should be given during the second year of life. Prior to entering school, every child should receive a booster dose of diphtheria and tetanus-toxoid combination and should be revaccinated against smallpox. The Department does not

manufacture influenza vaccine and does not recommend its routine use. Typhoid vaccine is now manufactured, and we expect soon to produce the triple typhoid-paratyphoid A and B vaccine for those who may wish its use. The employment of typhoid-paratyphoid vaccine should be limited to groups who are traveling abroad and should not be recommended as routine.

One of the newest activities of the Department is the furnishing of whole blood, plasma, gamma globulin and other fractions of whole blood free of charge to people in communities that have contributed blood on a voluntary basis to the State Blood Program. Because of the limited supply of blood, physicians are urged to select cases for the use of whole blood and blood fractions with care, so that these life-saving products will not be wasted. Supplies are made available first to the families of donors who have contributed during the past year and then to other people in the same community. In an emergency others may obtain these products but not routinely until their community has deposited with the State Blood Program a sufficient amount of blood to ensure that any calls they will make will not overdraw their account. Any physician desiring information regarding the use of any of the prophylactic or therapeutic products may call on the Division of Biologic Laboratories for consultation and advice. The Bacteriology Laboratory, previously located in the State House, and the Serology Laboratory, formerly located at Harvard Medical School, have recently moved to new quarters at 281 South Street, Jamaica Plain. Serology and Bacteriology Laboratories are now essentially merged in quarters adjacent to the Division of Biologic Laboratories.

Tuberculosis and Sanatoria This division is responsible for the administration of five hospitals and of our tuberculosis program in general. The tuberculosis program may be divided into three main categories. The first comprises diagnostic services, which are available to communities through the outpatient departments, fourteen consultation clinics and three mobile chest x-ray units. We are now making surveys of state institutions, industrial groups and certain selected communities. It is the objective of the Department to make a chest x-ray examination of every person over fourteen years of age within the next five to ten years to disclose active cases, which will be further confirmed by more detailed examinations. Cases that are found to be positive will be hospitalized in sanatoriums so as to afford the patients themselves a better and quicker chance of cure or arrest and to remove, if possible, the danger of infection of their own households and associates. The second aspect of the program has to do with the follow-up study of patients and contacts, including patients who have been discharged from institutions as arrested or against advice.

These must be followed to assure that they will receive the best possible care under the circumstances, that they do not break down, that they are pursuing an occupation that is not a hazard and that they are not a source of infection. The third phase of the tuberculosis program is that of sanatorium care. The Department pays a subsidy of \$5.00 per patient to county and municipal sanatoriums, provided they meet the established standards of the Department. At the present time all county and municipal sanatoriums are approved except the Lowell Isolation Hospital. The Department is responsible for the administration of the following institutions:

Rutland State Sanatorium, comprising 365 beds for the care of pulmonary tuberculosis. This was the first state tuberculosis hospital in the country. It should be rebuilt within the Greater Boston area, since it serves primarily the patients from the eastern part of the state.

North Reading State Sanatorium, with 240 beds, of which half are devoted to the care of tuberculosis of children and the other half will be devoted, as soon as personnel is available, to the care of acute rheumatic fever.

Lakeville State Sanatorium, with 304 beds, is devoted primarily to the care of extrapulmonary tuberculosis, such as that of the bones and joints and the kidneys. This institution also has special wards devoted to the care of patients with crippling conditions due to infantile paralysis and spastic paralysis. A limited number of acute cases are also received for hot-pack treatment.

Westfield State Sanatorium, with 189 beds for tuberculosis and 50 for cancer, receives cases of pulmonary tuberculosis and cancer and suspected cancer from the western part of the Commonwealth. A large outpatient department will receive any case referred to it either by a private physician or by a welfare organization.

Pondville Hospital, with 145 beds, was the first state cancer hospital established in the United States. A number of new buildings are needed to modernize the institution and to provide adequate living quarters for employees. Approximately six to seven thousand visits are made annually to the out-patient department.

Admission to these sanatoriums is through application made by the private physician and sent to the State House to the Division of Tuberculosis and Sanatoria. Anyone seeking advice about these institutions may call either the State House or the institutions directly.

Communicable Diseases. By law, the attending physician is required to report by name and address to the local board of health every case of disease declared dangerous to the public health. Boards of health furnish proper forms and may seek additional information. The Department of Public

Health issues minimum isolation and quarantine regulations, which are enforceable. Local boards of health may have more stringent regulations, but we do not recommend such additions. This division investigates all major cases of communicable diseases with the assistance of the district health officers as well as its own staff. In cases of outbreaks of serious nature, such as food-borne infection or infectious diarrhea of the newborn, a field unit is quickly organized and may call on the assistance of one of the medical schools or the Harvard School of Public Health. A diagnostic laboratory is available to which any physician may send specimens in kits provided by the Department.

This division is prepared to assist physicians in the diagnosis and treatment of more complicated cases of communicable disease. A list of consultants is available to determine the presence or absence of infantile paralysis. Consultants are not available, however, for cases in which paralysis is already present. A list of consultants is published annually in the *New England Journal of Medicine* or may be obtained from district health offices, from the local chapters of the National Foundation for Infantile Paralysis and from local boards of health.

The Division evaluates new immunization procedures, collects and analyzes morbidity and mortality data and issues periodic notices through the column of the Department in the *New England Journal of Medicine* of pertinent information on the incidence and prevalence of communicable diseases in the Commonwealth. Consultant and advisory service is available through its staff and that of our district health offices.

Local Health Administration. This is one of the newest as well as one of the largest divisions in the Department. In it are the bureaus of Public Health, Nursing, Nutrition, Sanitary Inspection and Medical Social Work. This division supervises the work of the eight district health offices. The personnel of the district health offices are available as consultants and advisers to the medical and nursing profession and to the local boards of health. They are also available to physicians in the assistance and diagnosis of communicable diseases on problems pertaining to the handling of these cases in general hospitals or in homes. At the request or recommendation of the attending physician the Nursing Bureau of this division will provide nursing care for patients sick in the home, and the Nutrition Bureau will prepare special diets to assist individuals or families with nutrition problems. The Social Service Bureau will furnish information to an attending physician on numerous problems such as adoptions. This bureau also assists physicians in making arrangements for convalescent, nursing or terminal care of patients or for temporary care of children when the mother is hospitalized. District Health Officers have by law certain functions that they must perform, such as inspection of hospitals and other institutions,

the investigation of major cases of communicable diseases, the routine and semiannual check-up on typhoid carriers and the promotion of public health in all the communities of the Commonwealth.

Veneral Diseases The Division of Venereal Diseases subsidizes twenty-five clinics throughout the State with the co-operation of local boards of health and hospitals. Through these clinics penicillin is made available for the treatment of every case of gonorrhea, syphilis and other venereal diseases. Any patient who cannot afford private treatment may be treated, and transportation to these clinics is also afforded to those unable to pay. The present treatment consists of 2,400,000 units of penicillin over a period of seven and half days, with 0.2 gm. of bismuth subsalicylate given intramuscularly every other day for five doses. Cases of venereal diseases are at present not required to be reported by name. They are reported directly to the Department of Public Health by initial or number. Physicians may report by name if they so desire. Cases that lapse treatment must be reported by name and address for follow-up by workers who are made available through state funds to private physicians in clinics. The law requires that a person desiring to be married must have a serologic blood test performed in an approved laboratory. The Department of Public Health, through the Division of Communicable Diseases, approves laboratories for serologic tests. Persons who have positive tests may marry, but the physician is obliged to inform both parties of the positive reaction and should report the patient to the Department. Physicians are further required to make an examination of the blood of all pregnant women. All specimens may be sent to the Department of Public Health or to approved laboratories. A list of approved laboratories may be obtained from the State House or from the district health offices.

The Department is now experimenting in the treatment of syphilis with penicillin in peanut oil and heeswax. Daily injections of 300,000 units over a period of eight or nine days are given. Preliminary reports on this method of treatment are encouraging.

An attempt is being made to rehabilitate prostitutes and other promiscuous persons. At times, the Department must resort to court action in cases of flagrant violation of the moral code.

Cancer and Other Chronic Diseases This division is responsible for conducting a cancer-control program and is assisted in the endeavor by the Massachusetts Medical Society and the American Cancer Society (Massachusetts Division), Inc. The program has three objectives: the prevention of cancer, its early recognition and prompt adequate treatment, and studies — biologic, clinical and epidemiologic — to learn more about the disease. The major parts of the program include maintaining a cancer registry, conducting cancer statistical research, furnish-

ing information to both the profession and the laity and service to cancer patients.

Two cancer hospitals, eighteen cancer diagnostic clinics and one contemplated cancer clinic, together with free-tissue diagnosis service to all physicians in the Commonwealth, comprise the service elements of the program. Free service at the clinics is limited to the medically indigent, but experience has shown that relatively few patients are able to pay. Through these clinics and the two hospitals the Department is seeing approximately 10 per cent of all cases of cancer in the Commonwealth.

Education of the public is maintained through local co-operative cancer-control committees, whose chief function is to arrange meetings at which local physicians are invited to speak on cancer. Many thousands of these meetings have been held, and I should like to take this opportunity to thank the physicians of Massachusetts for so freely contributing to this effort.

SPECIFIC SERVICES OFFERED TO PHYSICIANS

Postgraduate Education

Through funds made available by the United States Public Health Service and the Children's Bureau, the Department can offer physicians postgraduate training in public health. Physicians who have graduated from an approved medical school and who have had one or more years of internship are accepted in the Department in a training position during which they receive a salary of \$300 a month for a period of field orientation. Subsequently, if they prove their worth and wish to continue in public health, they may elect to attend any of the ten schools of public health in the United States for an academic year, working toward the degree of master of public health. During their stay at the school, they are paid their tuition, traveling expenses to and from the school, and a stipend equivalent to approximately \$300 a month. Physicians who are interested in obtaining such training are expected to pursue careers in public health in the state, local or voluntary health agencies in Massachusetts. Some training is offered to other professional groups. Selected persons may be given a second year of training in public health or in one of the allied fields, provided they expect to work with the state health agency in this field.

With the co-operation of the Massachusetts Medical Society, the Department has been sponsoring postgraduate education of physicians in practice, especially of veterans who have returned after several years of service. Educational facilities have been made available through the postgraduate teaching facilities of the Massachusetts Medical Society, the Sanders Theater programs and, on occasion, special teaching clinics conducted by the Cancer Clinics and special courses devoted to such fields as care of the premature infant, well-child con-

These must be followed to assure that they will receive the best possible care under the circumstances, that they do not break down, that they are pursuing an occupation that is not a hazard and that they are not a source of infection. The third phase of the tuberculosis program is that of sanatorium care. The Department pays a subsidy of \$5.00 per patient to county and municipal sanatoriums, provided they meet the established standards of the Department. At the present time all county and municipal sanatoriums are approved except the Lowell Isolation Hospital. The Department is responsible for the administration of the following institutions:

Rutland State Sanatorium, comprising 365 beds for the care of pulmonary tuberculosis. This was the first state tuberculosis hospital in the country. It should be rebuilt within the Greater Boston area, since it serves primarily the patients from the eastern part of the state.

North Reading State Sanatorium, with 240 beds, of which half are devoted to the care of tuberculosis of children and the other half will be devoted, as soon as personnel is available, to the care of acute rheumatic fever.

Lakeville State Sanatorium, with 304 beds, is devoted primarily to the care of extrapulmonary tuberculosis, such as that of the bones and joints and the kidneys. This institution also has special wards devoted to the care of patients with crippling conditions due to infantile paralysis and spastic paralysis. A limited number of acute cases are also received for hot-pack treatment.

Westfield State Sanatorium, with 189 beds for tuberculosis and 50 for cancer receives cases of pulmonary tuberculosis and cancer and suspected cancer from the western part of the Commonwealth. A large outpatient department will receive any case referred to it either by a private physician or by a welfare organization.

Pondville Hospital, with 145 beds, was the first state cancer hospital established in the United States. A number of new buildings are needed to modernize the institution and to provide adequate living quarters for employees. Approximately six to seven thousand visits are made annually to the out-patient department.

Admission to these sanatoriums is through application made by the private physician and sent to the State House to the Division of Tuberculosis and Sanatoria. Anyone seeking advice about these institutions may call either the State House or the institutions directly.

Communicable Diseases. By law, the attending physician is required to report by name and address to the local board of health every case of disease declared dangerous to the public health. Boards of health furnish proper forms and may seek additional information. The Department of Public

Health issues minimum isolation and quarantine regulations, which are enforceable. Local boards of health may have more stringent regulations, but we do not recommend such additions. CARCINOMA OF THE COLON AND RECTUM*

JAMES W. JAMESON, M.D.,† AND CLINTON R. MULLINS, M.D.‡

CONCORD, NEW HAMPSHIRE

THE purpose of this presentation is to give our experience with all the cases of carcinoma of the colon and rectum that have come under our observation from September, 1936, to September, 1946. This experience seems to be of interest since few reports from such small communities as ours (with a population of about 28,000) are forthcoming.

We have tried to follow the most generally accepted methods of management as judged from past experience, observation of procedures in use elsewhere and a study of current literature for improvements in technic and care. We have also attempted to emphasize the importance of nutritional restoration, replacement of vitamin deficiencies, blood transfusions as indicated, fluid balance and careful supervision for complications, both preoperatively and postoperatively. The anesthesia had been almost entirely spinal, either in one dose or fractional, given either by the surgeon and watched by a nurse anesthetist or by a physician who was not a specialist in anesthesia. There have been no serious accidents or failures in this respect. Local anesthesia has been used for preliminary cecostomy when needed.

Sulfaguanidine, sulfasuxidine and sulfathalidine have been used since their introduction, and it is believed that they offer an added factor of safety at operation.

Operative Technic

Catgut sutures have been employed in most cases. Cotton sutures have recently been used, with satisfactory results. Retention sutures of heavy silk or nylon have been placed in most cases but were not used in the 2 cases in which the wounds disrupted, they seem to be a necessary precaution. All anastomoses of the intestine were of the open type, interrupted silk being used for the serosal sutures. It is believed that the added exactness of the open anastomosis more than compensates for the possible danger of contamination. In 24 cases in which this was done there were no deaths and no signs of peritonitis. Local sulfonamide therapy has been employed in all cases of anastomosis—usually 20 per cent microform sulfathiazole suspension in amounts up to 20 cc.

Early ambulation has not been carried out in these cases. There have been no cases, however, showing clinical signs of phlebitis or pulmonary embolism. No case with clinical signs of pneu-

monia or atelectasis has been observed. Wound infection has not been troublesome.

Carcinoma of the Ascending Colon

There were 14 cases in all, including 12 male and 2 female patients, and of these only 9 cases were considered resectable at operation, in 5 cases that were deemed inoperable because of involvement of other structures and fixation, 1 having a large abscess, palliative procedures were performed. The resections were all done in one stage, in spite of varying degrees of obstruction. There were no postoperative deaths. In the 6 cases in which operation was done three or more years ago, 4 patients, or 66 per cent, are living and well. Of the 2 patients who died, 1 lived seventeen months and succumbed with signs of recurrence and the other lived 10 months. The latter had a cecostomy performed before being seen by us, so that the prognosis seemed poor from the beginning. Of the operations done since 1943, 1 is a recent case, 1 patient is living and well nine months postoperatively, and another died after six months of metastases. The only postoperative complication was infection of the operative wound in 1 case. It seems that carcinoma of the ascending colon presents greater difficulty in diagnosis than any other area for both the roentgenologist and the physician.

The following report is that of a patient in this group who also had a separate lesion in the left transverse colon, which was not discovered until later.

J. R. (C.H. 52512) a 47-year-old woman was admitted to the hospital on January 26, 1943. She gave a history of rectal bleeding 9 months before admission. She was anemic and received liver and iron for several months before and after that episode. About 2½ months before entry she began to have abdominal cramps and loose stools. A barium enema given shortly before admission showed a lesion of the ascending colon.

The past history was irrelevant.

Physical examination disclosed a pale patient with a firm slightly tender movable mass about 9 cm. in diameter in the region of the cecum.

Examination of the urine was negative. Examination of the blood revealed a red-cell count of 4,410,100 with a hemoglobin of 13.1 gm., and a white-cell count of 8600, with 58 per cent neutrophils, 27 per cent lymphocytes, 12 per cent monocytes and 3 per cent eosinophils.

At operation on February 2 the abdomen was explored through a right rectus-muscle-splitting incision. There was a typical growth in the cecum with no evidence of metastasis to the liver or local lymph nodes. The lesion was easily mobilized and removed, together with the terminal ileum and hepatic flexure of the colon and regional mesentery. An end-to-side ileotransverse anastomosis was carried out.

The pathological report showed a growth 6 cm. in its greatest diameter just distal to the ileocecal valve, involving about half the circumference of the bowel. Microscopic

Richard B. Cattell at the Lahey Clinic One polyp showed malignant changes Also of interest were 2 sisters, who had lesions of the descending colon

carcinoma of the Rectum

There were 33 cases in this group, with 19 male and 14 female patients Abdominoperineal resections were performed in 17 cases — one-stage in 16 and two-stage in 1, in these cases operations were done three or more years ago in 11, and 4 patients (36 per cent) are living and well There were no postoperative deaths, but serious complications were troublesome In 1 case the wound disrupted on the fifth day This patient had liver metastasis at the time of operation Another disruption occurred on the seventh day, with perforation of the small intestine and extensive soilage from the intestinal contents, repair of the perforation and suture of the abdominal wall were done in bed under local anesthesia, and the patient lived thirty-eight months without recurrence, dying of coronary thrombosis This patient also had two distinct lesions, one of the rectum and one of the sigmoid

One patient had a herniation of the small intestine through the pelvic floor, the obstruction being missed at the first operation This patient was living and well forty-four months after operation Another also had signs of obstruction postoperatively and was again operated on, but only extensive adhesions were found The adhesions were considered as possibly due to the sulfathiazole suspension used at the first operation This patient was well twenty-four months after operation

There were 2 cases in which only local excision was done In 1, in which a rectal polyp showed malignant changes, the patient was free of recurrence thirty-five months postoperatively The other patient had extensive papillary changes, microscopically malignant, and local resection was performed after wide exposure by splitting of the sphincters anteriorly and posteriorly This patient was free of recurrence and had no incontinence twenty-four months later Radical operation was refused in this case

Five cases were treated by radon seeds, 3 for palliative purposes, with little benefit, and 2 for possible cure One of the latter patients refused surgery, and the general condition of the other seemed too poor for operation Both had small lesions, which were found to be malignant at biopsy One was living and well eight years, and the other five and a half years after operation

Of 2 patients who were not treated, one died twenty-four hours after admission with perforation and peritonitis, and the other was almost moribund on admission

SUMMARY

Over a ten-year period 71 cases of carcinoma of the colon and rectum were seen Of these, 49 were deemed to be operable, 4 of which were not treated radically for varying reasons Forty-five were operated on for cure, with 1 postoperative death — a mortality of 2 per cent Twenty-eight of this group were treated three or more years ago, and 13 are still living and well — a three-year survival rate of 46 per cent Of 18 cases seen five or more years ago, 11 were treated for possible cure, and 7 were treated palliatively Five of the patients treated survived for five years or longer

The results leave much to be desired but are not wholly discouraging

DISCUSSION

DR. FRANK H. LAHEY (Boston) Three points ought to be stressed in connection with these cases, one of which has not been discussed. The principal one is that this is a favorable lesion, but even the satisfaction derived from the present good results ought not to mislead as regarding another fact that we have stressed again and again the relation of polyps to cancer and the need for everyone to think of polyps as possibly precancerous

Many patients have polyps. No one knows exactly what the incidence is, but it is probably at least 5 per cent. I urge again that every routine physical examination include a proctoscopic and sigmoidoscopic examination, which often discloses polyps that can be removed It is obvious that not all of them are removed but, on the other hand with each polyp that is removed the chances that the patient will have a cancer are reduced

Proctoscopic examination of colostomies should be carried out after abdominoperineal resection because it is easy to proctoscope a colostomy before the patient goes home. There are definite occasions on which polyps are demonstrated that can be removed and the patient may well be saved from another carcinoma.

Surgeons are urged to review their personal experiences in operating on patients with carcinoma of the colon and rectum. I know that I have regarded as inoperable cases of carcinoma of the colon or rectum that would be considered operable today in terms of possible cure

The difference between growth by extension and true metastasis is again stressed. I have in the hospital today a woman who is ready to leave she had a carcinoma of the rectosigmoid that had perforated into the bladder She has had a resection of the sigmoid removal of the left tube and ovary ligation of the left ureter and resection of two thirds of the bladder

We need to think that these extensive procedures could not be done, but we have now done combined abdominopelvic resections of the rectum, together with total hysterectomy and removal of the tubes and ovaries In 90 cases. Often the uterus is involved only by contact extension Carcinoma of the sigmoid is frequently found on top of the bladder and can be removed by local removal of the portion of the bladder involved as in this series of cases recorded by Drs. Jameson and Mullins They illustrate what can be done in relatively small communities if this group of cases can go into a limited number of hands

We must face facts even if we do not like them, as I have learned over the years. In the beginning I was not adept at operations on the colon and rectum It is only by experience that one acquires the ability to handle these late cases — that is those with contact extensions to the jejunum those in which the perineal fat is involved (in which all the perineal fat can be excised) and those that, by contact have involved other loops of bowel

I therefore re-emphasize the facts that these patients who have no other hope, provided they do not have distant metastases and the growth is only local should all be given much better chances with more radical approaches than

we have often given them in the past, and that many of them will probably enter the group with five-year non-recurrence rates

DR WALTER G PHIPPEN (Salem, Massachusetts) I know that you are interested in the postoperative morbidity that results from the better preoperative and postoperative care with the use of antibiotic drugs in resection of the colon. Our last 8 cases of resection of the colon are of particular interest

From December 21, 1945, through September 17, 1946, 8 patients, whose ages ranged from thirty-four to eighty-two years and whose average age was fifty-six years, were operated on. There were 3 cases of carcinoma of the sigmoid, 1 of carcinoma of the rectosigmoid, 1 of carcinoma of the transverse colon, 1 of carcinoma of the descending colon and 1 of obstruction by a fibrofatty mass due to infolding of the wall of the bowel after a resection of a cancer of the ascending colon and ileocolostomy by the Mikulicz technic, as well as 1 case of scar constriction of the sigmoid following a Mikulicz resection of a carcinoma of the sigmoid

In all cases carcinoma of the large bowel was present or had been present.

The 2 patients in whom the lesions had previously been resected showed no evidence of recurrent disease

Sulfasuxidine was used in 3 cases, with an abnormal reaction to the drug in 1. Sulfathalidine was used in 5 cases, with no untoward reaction. The dosage for both drugs was the same—namely, 6 gm a day given in 1-gm doses at intervals of four hours. Usually, at 10 p.m. the dose was 2 gm, and the 2 a.m. dose was omitted. In the first 5 cases the drug was given for an average of three days before operation, but in the last 3, which have occurred during the past three months, sulfathalidine was given for ten days before surgery was done. The average total preoperative dose was 17 gm in the first 5 patients, and 62 gm in the last 3

In the patient who appeared to be sensitive to sulfasuxidine the drug was given into a defunctioned left colon. On the following day the temperature rose to 103°F, without a corresponding elevation of the pulse or any other signs or symptoms. Two days later the temperature was normal, and the resection was done without further complications. This patient was given 6 gm of sulfasuxidine a day, by mouth, for two days before closure of the colostomy. She seemed to have no drug fever at that time, but the temperature rose to 102°F each day for three days after the colostomy had been closed—there was no wound sepsis or other explanation for the fever. This case is the only one of this group in which the temperature rose above 100.6°F after large-bowel anastomosis by the open technic

In the patient with carcinoma of the descending colon, a transverse colostomy had previously been performed. In the remaining 7 cases, cecostomy was performed in 5—in 3 as a complementary procedure, in 1 as an emergency for complete obstruction of the sigmoid and in 1 as a preliminary operation to resection of the transverse colon

In each case the colon was widely opened and sutured by the open technic. Resection of the bowel was done in each case except the one with obstruction following a Mikulicz right colectomy

One resection of the sigmoid for scar obstruction was done without proximal vent except that provided by a Harris tube in the small bowel

Gas was passed by rectum in 7 of the 8 cases in an average of three and a half days after the resection, and a bowel movement by rectum occurred on the average in slightly less than seven and a half days

All wounds were treated by the method of delayed primary closure, the fascia being closed with interrupted No. 30 cotton suture, and the skin edges being closed by drawing up of the sutures or by clips on the second day. There was no wound sepsis

CLINICAL NOTE

TUBERCULOSIS IN THE AGED

REPORT OF A CASE

DAVID C DITMORE, M.D.*

BOSTON

MILLER and Henderson¹ state that one of the greatest deficiencies in tuberculosis control has been the failure to make sufficient use of case-finding technics in the discovery of the elderly person with undiagnosed pulmonary tuberculosis. Meyers² believes that the presence of communicable pulmonary tuberculosis in persons over fifty years of age is higher than that in any other age period. The frequency of tuberculosis in the aged has been noted by others.³⁻⁵

Laird⁶ observes that the death rate from tuberculosis per 100,000 population in people over seventy years of age in 1940 was 91 for men and 68 for women and that, since there are 4,250,000 people over seventy years of age in the United States, the total number of deaths is not inconsiderable. Jennings⁷ asserts that one of the persistent misconceptions held by the general public about tuberculosis

is that it never occurs in older age groups. He claims that even in medical circles the impression is current that old age affords protection against tuberculosis. Of 7212 patients admitted to Glen Lake Sanatorium, however, 13.8 per cent were over fifty years of age⁷, in 1 of these, a woman, the diagnosis was made for the first time at the age of sixty-four. Mariette⁸ states that the oldest patient he remembers was a man ninety-four years of age at the time of admission to an institution.

The following case illustrates the necessity of bearing constantly in mind the possibility of tuberculosis in the aged as well as in the young patient. Such cases, when unrecognized, represent a danger to the community.

H. N. M., a 71-year-old man, was referred for examination on December 27, 1946. He stated that until 7 weeks previously he had always been perfectly well. Soreness at defecation had been present since that time, and it had been difficult to keep himself clean because of a discharge from the anus. He denied ever having a temperature, cough, sputum or weight loss.

Examination of the anal canal disclosed the presence of two ulcers. One, located in the anterior commissure, was irregular in outline but measured approximately 1.5 cm in the widest diameter. The other, which was located on the left posterior lateral quadrant of the anal canal and measured approximately 3 cm in length and 2 cm in width, had the appearance of being the result of pressure from a pendulous external hemorrhoid extending across the canal from right to left, the point of contact producing a pressure necrosis.

The edges of both ulcers consisted of a thin layer of skin without evidence of unusual thickening, induration or undermining. The base was covered with small tufts of rather indolent-appearing granulation tissue, which did not bleed easily on trauma. The surface was bathed with a copious grayish-yellow discharge that was easily removed with a

*Instructor, Department of Proctology, Boston University School of Medicine; proctologist, Carney Hospital; consulting proctologist, Brookline Hospital.

cotton-tipped applicator. Because of the unusual appearance of the ulcers they were excised and on examination showed changes typically present in tuberculosis. Ordinary treatment for 4 weeks produced no cure of the ulcers but complete healing occurred 2 weeks after the institution of streptomycin therapy.

On questioning the patient recalled that 2 years previously while having financial difficulties he had lost considerable weight, but he had attributed this to worry. He also admitted having a hacking cough in the morning and some sputum which he thought to be due to an old sinus infection.

A study of the sputum disclosed the presence of many colonies of *Mycobacterium tuberculosis*. X-ray examination of the chest showed a profuse mottling of all lobes of both lungs having much the appearance of miliary tuberculosis.

MEDICAL PROGRESS

"FOLIC ACID" PTEROYLGLUTAMIC ACID AND RELATED SUBSTANCES (Concluded)*

FREDERICK SARGENT, II, M.D.†

CHICAGO

THERAPEUTIC USES

The diseases in which pteroylglutamic acid has proved to be therapeutically effective are as follows: blood dyscrasias, including Addisonian pernicious anemia (hematologic phase), megaloblastic anemia of infancy, (?) refractory megaloblastic anemia, (?) tropical macrocytic anemia, nutritional neutropenia and nutritional macrocytic anemia, both primary (due to poor diet) and secondary (associated with pregnancy, pellagra, some cases of sprue syndrome, chronic alcoholism, gastric carcinoma and gastric resection), and gastrointestinal disturbances, such as certain cases of tropical and nontropical sprue, chronic diarrhea and celiac disease.

Conditions that have failed to respond to pteroylglutamic acid are certain blood dyscrasias (the neurologic phase of Addisonian pernicious anemia, idiopathic and secondary hypoplastic and aplastic anemia, hypochromic anemia of iron deficiency, anemia associated with cancer, leukemia and lymphoma, leukopenia following x-ray therapy, idiopathic agranulocytosis, agranulocytosis due to sulfonamides, thiouracil, arsenicals, aminopyrine and so forth and idiopathic and symptomatic thrombocytopenic purpura) and gastrointestinal disturbances, including idiopathic ulcerative colitis and certain cases of celiac disease, nontropical sprue and tropical sprue.

Only the more important of these diseases are considered below.

Addisonian Pernicious Anemia

Addisonian pernicious anemia is characterized by a disturbance of hematopoiesis and by combined-

system disease. Because these two phases respond differently to therapy with pteroylglutamic acid, each must be considered separately. Many cases of pernicious anemia in hematologic relapse have already been treated with this vitamin, with results that may be summarized as follows. In the peripheral blood, the reticulocytes begin to increase on the fourth to the sixth day, reaching a peak between the seventh and tenth days. The reticulocyte crisis is followed by a gradual rise in the red-cell count and the hemoglobin. In many cases the total white-cell count mounts, and the platelets increase in number. Simultaneously, the bone marrow undergoes a change from the characteristic maturation arrest to a normoblastic picture. A number of investigators have reported that, in spite of prolonged treatment or large doses of pteroylglutamic acid, the reticulocyte crisis is submaximal and the red-cell count and hemoglobin never reach normal values.¹¹⁻¹⁴ If such patients are further treated with liver extract, the red-cell count and hemoglobin rapidly reach normal values. Meyer¹⁵ reports that in a few cases small oral doses of pteroylglutamic acid (5 mg daily), in addition to 0.5 unit of liver extract, often give a reticulocytosis greater than anticipated and that with such therapy the remission is complete. In contrast, Davidson and Girdwood¹⁶ have occasionally achieved excellent hematopoietic responses with as little as 1 mg of pteroylglutamic acid orally. Along with these hematologic improvements, the patient experiences a feeling of well-being, and the appetite returns to normal. Such symptoms as burning of the tongue, weakness, easy fatigability and dyspnea rapidly disappear.^{2, 11, 12, 17}

In contrast to the success in managing the hematologic phase, treatment of the neurologic manifesta-

*Based on a talk presented at a meeting of the Berg Society of Boston University School of Medicine, Boston, on April 7, 1947.

†Formerly fourth-year student, Boston University School of Medicine.

we have often given them in the past, and that many of them will probably enter the group with five-year non-recurrence rates

DR WALTER G PHIPPEN (Salem, Massachusetts) I know that you are interested in the postoperative morbidity that results from the better preoperative and postoperative care with the use of antibiotic drugs in resection of the colon. Our last 8 cases of resection of the colon are of particular interest

From December 21, 1945, through September 17, 1946, 8 patients, whose ages ranged from thirty-four to eighty-two years and whose average age was fifty-six years, were operated on. There were 3 cases of carcinoma of the sigmoid, 1 of carcinoma of the rectosigmoid, 1 of carcinoma of the transverse colon, 1 of carcinoma of the descending colon and 1 of obstruction by a fibrofatty mass due to infolding of the wall of the bowel after a resection of a cancer of the ascending colon and ileocolostomy by the Mikulicz technic, as well as 1 case of scar constriction of the sigmoid following a Mikulicz resection of a carcinoma of the sigmoid

In all cases carcinoma of the large bowel was present or had been present.

The 2 patients in whom the lesions had previously been resected showed no evidence of recurrent disease.

Sulfasuxidine was used in 3 cases, with an abnormal reaction to the drug in 1. Sulfathalidine was used in 5 cases, with no untoward reaction. The dosage for both drugs was the same — namely, 6 gm a day given in 1-gm doses at intervals of four hours. Usually, at 10 p.m. the dose was 2 gm, and the 2 a.m. dose was omitted. In the first 5 cases the drug was given for an average of three days before operation, but in the last 3, which have occurred during the past three months, sulfathalidine was given for ten days before surgery was done. The average total preoperative dose was 17 gm in the first 5 patients, and 62 gm in the last 3.

CLINICAL NOTE

TUBERCULOSIS IN THE AGED

REPORT OF A CASE

DAVID C. DITMORE, M.D.*

BOSTON

MILLER and Henderson¹ state that one of the greatest deficiencies in tuberculosis control has been the failure to make sufficient use of case-finding technics in the discovery of the elderly person with undiagnosed pulmonary tuberculosis. Meyers² believes that the presence of communicable pulmonary tuberculosis in persons over fifty years of age is higher than that in any other age period. The frequency of tuberculosis in the aged has been noted by others.³⁻⁵

Laird⁶ observes that the death rate from tuberculosis per 100,000 population in people over seventy years of age in 1940 was 91 for men and 68 for women and that, since there are 4,250,000 people over seventy years of age in the United States, the total number of deaths is not inconsiderable. Jennings⁷ asserts that one of the persistent misconceptions held by the general public about tuberculosis

*Instructor, Department of Proctology, Boston University School of Medicine, proctologist, Carney Hospital; consulting proctologist, Brookline Hospital.

In the patient who appeared to be sensitive to sulfasuxidine the drug was given into a defunctioned left colon. On the following day the temperature rose to 103°F., without a corresponding elevation of the pulse or any other sign or symptoms. Two days later the temperature was normal, and the resection was done without further complications. This patient was given 6 gm of sulfasuxidine a day, by mouth, for two days before closure of the colostomy. She seemed to have no drug fever at that time, but the temperature rose to 102°F. each day for three days after the colostomy had been closed — there was no wound sepsis or other explanation for the fever. This case is the only one of this group in which the temperature rose above 100.6°F. after large-bowel anastomosis by the open technic.

In the patient with carcinoma of the descending colon, a transverse colostomy had previously been performed. In the remaining 7 cases, cecostomy was performed in 5 — in 3 as a complementary procedure, in 1 as an emergency for complete obstruction of the sigmoid and in 1 as a preliminary operation to resection of the transverse colon.

In each case the colon was widely opened and sutured by the open technic. Resection of the bowel was done in each case except the one with obstruction following a Mikulicz right colectomy.

One resection of the sigmoid for scar obstruction was done without proximal vent except that provided by a Hartmann tube in the small bowel.

Gas was passed by rectum in 7 of the 8 cases in an average of three and a half days after the resection, and a bowel movement by rectum occurred on the average in slightly less than seven and a half days.

All wounds were treated by the method of delayed primary closure, the fascia being closed with interrupted No. 30 cotton suture, and the skin edges being closed by drawing up of the sutures or by clips on the second day. There was no wound sepsis.

is that it never occurs in older age groups. He claims that even in medical circles the impression is current that old age affords protection against tuberculosis. Of 7212 patients admitted to Glen Lake Sanatorium, however, 13.8 per cent were over fifty years of age⁷, in 1 of these, a woman, the diagnosis was made for the first time at the age of sixty-four. Mariette⁸ states that the oldest patient he remembers was a man ninety-four years of age at the time of admission to an institution.

The following case illustrates the necessity of bearing constantly in mind the possibility of tuberculosis in the aged as well as in the young patient. Such cases, when unrecognized, represent a danger to the community.

H. N. M., a 71-year-old man, was referred for examination on December 27, 1946. He stated that until 7 weeks previously he had always been perfectly well. Soreness at defecation had been present since that time, and it had been difficult to keep himself clean because of a discharge from the anus. He denied ever having a temperature, cough, sputum or weight loss.

Examination of the anal canal disclosed the presence of two ulcers. One, located in the anterior commissure, was irregular in outline but measured approximately 1.5 cm. in the widest diameter. The other, which was located on the left posterolateral quadrant of the anal canal and measured approximately 3 cm. in length and 2 cm. in width, had the appearance of being the result of pressure from a pendulous external hemorrhoid extending across the canal from right to left, the point of contact producing a pressure necrosis.

The edges of both ulcers consisted of a thin layer of skin without evidence of unusual thickening, induration or undermining. The base was covered with small tufts of rather in-dolent-appearing granulation tissue, which did not bleed easily on trauma. The surface was bathed with a copious grayish-yellow discharge that was easily removed with a

factor described by Castle. In addition, there is no anemia relieved by pteroylglutamic acid that does not also respond to therapy with liver extract.² These points comprise a list of disadvantages against the pteroylglutamic acid as the "new hope for anemic patients." Do any advantages accrue from the use of this vitamin? Two features have been suggested: oral therapy obviates repeated injections, but weighed against the possibility of neurologic relapse, this can scarcely be considered an advantage, and pteroylglutamic acid may be employed when patients are allergic to liver extract.² Against the latter consideration is the fact that patients allergic to pork-liver extract react satisfactorily to beef-liver extract given parenterally.⁴

Blood Dyscrasias of Nutritional Origin

The megaloblastic anemias of nutritional origin that respond to pteroylglutamic acid may be due either primarily to a poor diet or to secondary nutritive failure consequent to anorexia, poor absorption and utilization or increased requirements. The secondary cases are seen in such conditions as pellagra, pregnancy, the sprue syndrome, chronic alcoholism and gastric carcinoma. In cases of sprue, as pointed out below, the hematopoietic disturbance frequently fails to respond to therapy with pteroylglutamic acid. When neutropenia or thrombocytopenia occurs as a manifestation of nutritive failure, an increase in leukocytes and platelets will follow the administration of pteroylglutamic acid. If, however, the anemia is normoblastic or hypochromic (due to an iron deficiency) and the neutropenia and thrombocytopenia are idiopathic or secondary, administration of this nutrient effects no hematologic response.

Refractory Megaloblastic Anemia

Some cases of macrocytic anemia that present blood and bone-marrow pictures indistinguishable from pernicious anemia have no achlorhydria and fail to respond to parenteral purified liver extract. Such cases, however, respond to administration of crude extracts and yeast. These cases, which are called "refractory megaloblastic anemia," probably arise from poor dietary habits. Wills and her associates⁴ have described such cases from India, suggesting that the name "tropical macrocytic anemia" be used to designate the condition. Wills⁴ has produced a macrocytic anemia with a megaloblastic marrow in monkeys by the administration of a poor diet similar to that eaten by human patients with tropical macrocytic anemia. This monkey anemia is refractory to parenteral purified liver, but responds to a relatively purified substance from yeast preparations. Watson and Castle⁴ suggest that this factor be called the Wills factor. The relations between the Wills factor and pteroylglutamic acid or between Wills monkey anemia and vitamin M deficiency have not been established,

but some workers have assumed that the two substances — pteroylglutamic acid and the Wills factor — are closely related, if not identical.⁵

One test of the relation between these substances is whether or not refractory megaloblastic anemia will respond to the administration of pteroylglutamic acid. Some cases called "refractory megaloblastic anemia" have been successfully treated with pteroylglutamic acid, but the criteria for so designating these particular cases is not clear. Two cases in this series seemed to fulfill the criteria for a diagnosis of refractory megaloblastic anemia. The patients showed a partial hematologic response to pteroylglutamic acid and were completely cured by further treatment with crude liver extract. One patient had a marked reticulocytosis on two occasions three weeks apart after treatment with purified liver extract, although there was no appreciable change in the red-cell count or the hemoglobin.⁷ One wonders if this case might not also have responded to purified liver extract if more than two injections had been tried. The results of this study suggest, however, that the Wills factor and pteroylglutamic acid are not identical.

Aplastic Anemia

Although most authors^{1, 2, 8} report that aplastic anemia does not respond to pteroylglutamic acid, a few long-standing cases have shown variable but incomplete remissions following prolonged treatment with massive doses of pteroylglutamic acid.⁴ The possibility that these patients were not merely undergoing spontaneous remissions was not satisfactorily ruled out.

Sprue Syndrome

The sprue syndrome consists of celiac disease in children and tropical and nontropical sprue in adults. There are a variety of reports in the literature concerning the response of this syndrome to pteroylglutamic acid.

Six cases of celiac disease have been treated with pteroylglutamic acid. In 3, a megaloblastic anemia accompanied the gastrointestinal disturbance. These cases have been reported only in summary, but they apparently responded with rapid clinical and hematologic improvement.⁹⁻¹¹ Three other patients with hypochromic anemia were not benefited by pteroylglutamic acid.¹¹

In the cases of nontropical and tropical sprue, there is likewise wide divergence of opinion regarding the usefulness of pteroylglutamic acid. So far as the associated anemia is concerned, some investigators¹²⁻²² report striking improvement, whereas others²³⁻³¹ report no improvement. Part of the variation in response seems to be due to the degree of anemia at the beginning of treatment with pteroylglutamic acid. This vitamin fails to effect a complete remission of the anemia. If the anemia is severe, there will be striking improvement, but the

remission will be incomplete. If the anemia is only moderate (a red-cell count of about 4,000,000) there may be no response. These results suggest that in some cases of the sprue syndrome there is a deficiency of the Wills factor, as well as of pteroylglutamic acid. Many authors^{16, 23, 29, 38, 51-54} report that the clinical improvement in cases of tropical and nontropical sprue is remarkable and dramatic. There is rapid restoration of appetite and sense of well-being. Epigastric distress disappears. More slowly, the body weight is restored to normal. Some cases fail to respond permanently, although they may show temporary improvement.⁵⁵

Together with clinical improvement, there is marked improvement in gastrointestinal function. The bowel movements decrease in number and become normal in odor, color and consistence. The gastrointestinal mucosa is restored to its normal condition. Davidson and Girdwood⁵¹ point out that in their series of 7 cases the most remarkable improvement of intestinal function occurred about the fifth day after the beginning of treatment with pteroylglutamic acid.

Metabolic improvement has also been noted by some workers. The blood levels of carotene and vitamins A and E are increased.⁷ Some workers^{7, 38} have reported restoration of glucose tolerance to normal. Others⁵¹ have been unable to detect much change in fat absorption.

Further clinical study will be required before a final evaluation of the place of pteroylglutamic acid in the management of the sprue syndrome can be made. The hematologic results suggest that some other substances are necessary for a complete remission. The complicating roles of intestinal infestation with bacteria and parasites and of poor nutrition have not been adequately studied. A recent report by Suárez et al³⁸ emphasizes the fact that the response of this syndrome to pteroylglutamic acid may be facilitated by an accompanying adequate diet.

Other Gastrointestinal Disturbances

Carruthers¹⁹ reports that 6 cases of chronic diarrhea of six weeks' to six months' duration of diverse etiology responded promptly to pteroylglutamic acid. All these patients had failed to respond to specific or symptomatic treatment. When 40 to 60 mg of pteroylglutamic acid had been given daily by mouth for two to five days, the diarrhea rapidly cleared, and there was general clinical improvement. The author suggests that a nutritional factor probably prolonged the abnormal stools.

Five cases of idiopathic ulcerative colitis have been treated unsuccessfully with pteroylglutamic acid.²⁷ Two of these patients apparently became worse during the course of therapy.

Cancer

From the experimental laboratory comes suggestive evidence that pteroylglutamic acid and related substances play a role in the growth of neoplastic tissue. Lewisohn and his associates⁵⁶ have shown that, in spontaneous breast cancer in mice, pteroyltriglutamic acid (fermentation *L. casei* factor) given intravenously daily in doses of 5 mg for four to six weeks caused complete regression of the neoplastic growth in about a third of the test animals. Pteroylglutamic acid (liver *L. casei* factor) in doses of 5 and 100 mg intravenously did not cause appreciable regression of neoplastic tissue. In fact, as compared with the controls, the incidence of lung metastases seemed greater. Perhaps other pteroylpolyglutamic acids that will prove efficacious in the treatment of human cancer will be synthesized.

SUMMARY

A review of the current literature reveals that the newest member of the vitamin B complex—popularly called "folic acid"—may prove effective in the management of a variety of blood disorders and certain abnormal gastrointestinal conditions.

This vitamin has been isolated and synthesized. Its chemical name is pteroylglutamic acid. Pteroylglutamic acid is identical with the *Lactobacillus casei* factor necessary for growth of *L. casei*, vitamin B₉ necessary for growth and hematopoiesis in the chick and vitamin M, which prevents cytopenia and a fatal sprue-like syndrome in monkeys. The related substances, pteric acid and pteroyltriglutamic acid (the active principle in fermentation *L. casei* factor), have been synthesized. The active material in the vitamin B₉ conjugate (or "folic acid" conjugate) has been identified as pteroylheptaglutamic acid, but this heptapeptide has not yet been synthesized. A compound containing thirteen molecules of glutamic acid has also been isolated from yeast.

An enzyme that hydrolyzes the tripeptides and heptapeptides to glutamic as well as pteroylglutamic acid has been discovered. This enzyme, known as vitamin B₉ conjugase, is abundant in such animal tissues as liver, kidney, pancreas and bone marrow.

Foods have been found to contain an unidentified substance—conjugase inhibitor—that impedes the hydrolytic activity of the enzyme vitamin B₉ conjugase.

Pteroylglutamic acid is widely distributed in nature but the amount present even in the best sources, such as spinach and liver, is only of the order of 100 microgm per 100 gm. The amount of pteroylglutamic acid in the ordinary diet is far less than that which is therapeutically effective. Until the nutritional requirements for this vitamin are known, however, a final evaluation of the richness of the nutrient in nature cannot be made.

Most of the naturally occurring vitamin is present as pteroylheptaglutamic acid

The important deficiency symptoms due to lack of this essential nutrient are failure of growth, cytologic disturbances and gastrointestinal disorders. The mode of action of pteroylglutamic acid is unknown, but it has been shown that although the heptapeptide is not efficiently utilized by patients with Addisonian pernicious anemia, pteroylglutamic acid can be utilized to some extent. The inability to make use of the heptapeptide is apparently due to failure to neutralize conjugase inhibitor

Pteroylglutamic acid is nontoxic for animals and is without toxic effect in large doses given orally or intramuscularly to man. Intravenous administration to human patients, however, is not recommended because of several cases of shock-like reaction that have followed when this route has been used

The currently recommended therapeutic dosage is 10 mg orally each day. For maintenance 5 to 10 mg daily has been found effective in most cases

Pteroylglutamic acid has proved effective in the treatment of a variety of blood dyscrasias, including Addisonian pernicious anemia, nutritional macrocytic anemia and neutropenia, macrocytic anemias of infancy and pregnancy and macrocytic anemias following gastric resection. The evidence for the response of refractory megaloblastic anemia to pteroylglutamic acid is still incomplete. An occasional case of aplastic anemia may respond to this vitamin

There is no anemia that does not respond to pteroylglutamic acid that does not also respond to liver extract

Pteroylglutamic acid does not cause a neurologic remission, nor does it prevent a neurologic relapse among patients with Addisonian pernicious anemia. Indeed, in some cases it seems to precipitate or cause a sudden outbreak of symptoms and signs due to predominant disturbance in the posterior columns. For these reasons, management of Addisonian pernicious anemia with pteroylglutamic acid is not recommended

Pteroylglutamic acid has no place in the management of hypochromic anemia due to iron deficiency, anemias associated with cancer, leukemia and lymphomas, and idiopathic and secondary (symptomatic) hypoplastic anemia, aplastic anemia, agranulocytosis and thrombocytopenic purpura

Evaluation of the effectiveness of pteroylglutamic acid in the treatment of the sprue syndrome is difficult, for different investigators have reported both successes and failures. More exact definition

of the clinical entities being studied is probably needed

Some cases of "chronic diarrhea" due to nutritive failure are benefited by pteroylglutamic acid

No benefit accrues from the use of this nutrient in idiopathic ulcerative colitis. In fact, some patients seem to be made worse by such treatment.

Because fundamental knowledge concerning the action of pteroylglutamic acid is still limited and because a full clinical trial has not been made, it is too early to venture an opinion on the final place of this nutrient in therapeutics

I am indebted to Drs. William B. Castle and Lionel Berk, of the Boston City Hospital, for assistance in the preparation of this review

CASE 33451

PRESENTATION OF CASE

A seventy-six-year-old woman was admitted to the hospital because of abdominal pain.

For three years the patient had attacks of pain in the right lower quadrant of the abdomen, lasting only a few hours and associated with some constipation during these attacks. Eight days before admission, while riding in a car, she had a brief attack of pain, and finally, three days later, the pain became persistent. It radiated from the right lower quadrant to the back and to the left side of the abdomen but was not crampy in character. It was associated with nausea and vomiting of all solid food. There was no bowel movement in this interval, but she was able to pass gas.

The past illnesses and operations included an appendectomy thirty-five years before entry, a left salpingo-oophorectomy before entry, thyroidectomy twenty years before entry and a coronary thrombosis nine years before entry. She had had a Parkinsonian tumor for years. She had anginal attacks and had recently been taking digitalis.

Physical examination revealed a well nourished, dehydrated woman with a Parkinsonian tremor of the left arm and leg. The heart was enlarged, the border of cardiac dullness extending to the left. The whole abdomen was tender, especially in the right lower quadrant, where there was an exquisitely tender palpable mass measuring about 9 cm in diameter. This mass was also palpated in the right fornix on pelvic examination. Peristalsis was normal.

The temperature was 98°F, the pulse 95, and the respirations 22. The blood pressure was 250 systolic, 120 diastolic.

Examination of the blood disclosed a hemoglobin of 16 gm and a white-cell count of 11,400, with 86 per cent neutrophils. The nonprotein nitrogen was 47 mg, the fasting blood sugar 112 mg per cent, the total protein 6.5 gm per 100 cc, and the chloride 9 milliequiv per liter. A routine urine examination was negative.

A plain film of the abdomen showed gas-filled loops of small and large bowel. No gas was seen in the left colon distal to the hepatic flexure.

An operation was performed six hours after admission.

DIFFERENTIAL DIAGNOSIS

DR. MARSHALL K. BARTLETT. May we see the x-ray films?

DR. STANLEY M. WYMAN. The gas-filled colon described is seen extending from the region of the cecum to the splenic flexure. I cannot trace it with certainty below that point. There is some gas in the small bowel, but the bowel does not appear dilated. There are no areas of unusual calcification. I cannot outline the mass that is described.

DR. BARTLETT. I was hoping for more help but must proceed with what is given. This patient was seventy-six years old and had a past history of two laparotomies and, in the past three years, attacks of pain in the right lower quadrant, usually lasting only a short time. The attack that brought her to the hospital lasted for five days, and the pain was described as always being in the right lower quadrant with radiation to the back and left side. It was not crampy, but had been associated with vomiting. What processes would cause that picture, together with the physical finding of an exquisitely tender mass palpable in the right lower quadrant and also felt by pelvic examination? Of course the first thing that comes to mind in a person with previous abdominal surgery is intestinal obstruction. Favoring that is the fact that she had not had a bowel movement for five days, although she had been able to pass gas during that period. To explain the mass we must assume that she had a loop of bowel that in some way became incarcerated or strangulated. It seems to me that at the end of five days with a situation of that kind there would have been more x-ray evidence of dilated small bowel than we have. I do not see how we can explain this picture of intestinal obstruction on the basis of something in the colon. Because of the situation in the right lower quadrant it would have to be something in the cecum presumably. Certainly, from the x-ray picture there was more gas in the right colon than elsewhere in the bowel. I therefore do not believe that this case will fit that picture.

What else could it have been? The appendix has been ruled out because it had been removed. There is the technical possibility of a residual section of appendix that developed into an abscess, but I cannot quite picture this as an abscess in the right lower quadrant. The normal temperature and moderate elevation of the white-cell count seem to me rather against something that had perforated and formed an abscess. Another fairly remote possibility is a Meckel's diverticulum. If it were diverticulitis of the sigmoid it would be more likely to be on the other side. A single diverticulum of the cecum is occasionally seen but is certainly rare, and again one would have to assume that it started with an acute inflammatory process with perforation and

abscess formation I think that the picture would have been a little different if this had been an abscess from any source

Regional enteritis must be thought of, but there is no particular feature of the history to point in that direction I suppose that in that condition a palpable mass can be formed, but I do not believe that it would have been of the type described in this case unless, again, it had perforated, with abscess formation

How about the pelvis as a source of this patient's problem? The left tube and ovary had been removed for a condition the nature of which we do not know To the best of our knowledge the right tube and ovary and the uterus were still present. Nothing is said in the history about the menstrual cycle We can assume, however, that the menopause had occurred many years previously It seems to me that an ovarian cyst is a definite possibility At her age that is more likely than a fibroid with a twisted pedicle I therefore believe the diagnosis of a twisted cyst best explains the sudden onset, the presence of an exquisitely tender mass at the end of five days, the normal temperature and the moderate elevation of the white-cell count

CLINICAL DIAGNOSIS

Twisted ovarian cyst.

DR BARTLETT'S DIAGNOSIS

Ovarian cyst, with twisted pedicle

ANATOMICAL DIAGNOSES

Carcinoids of ileum, with metastasis to mesenteric lymph nodes
Volvulus of ileum

PATHOLOGICAL DISCUSSION

DR. FRANCIS INGERSOLL My preoperative diagnosis was a twisted ovarian cyst When the abdomen was opened a gangrenous loop of small bowel presented On the mesenteric border of the bowel there was a hard area, and deep in the mesentery of the bowel there was a similar hard mass Farther up in the ileum there was a small nodule in the bowel wall The bowel was infarcted because of a three-quarter turn at the level of the mass in the mesentery Inspection of the ovaries and exploration of the abdomen failed to show any evidence of cancer or evidence of anything that might be connected with the two nodules previously mentioned Three feet of gangrenous terminal ileum were resected, and a side-to-side anastomosis between ileum and cecum was performed

DR. BENJAMIN CASTLEMAN The specimen we received was a loop of bowel, about 90 cm long, the middle third of which was thickened and gangrenous This gangrenous loop was twisted and adherent around an infiltrating mesenteric mass On opening the bowel we found in the region of the interad-

herence a submucosal tumor about 2.5 cm in diameter invading the wall of the bowel, but there was a definite space between the mesenteric mass and this nodule We noted a smaller but similar nodule about 25 cm away from the first nodule

Microscopical examination of these two tumors showed them to be argentaffinomas or carcinoids, and the mesenteric mass proved to be a metastasis from one of the tumors The carcinoid of the small bowel is a slowly growing tumor, and this one must have been present for years, finally metastasizing to one of the regional nodes It was the mesenteric metastasis that had produced the adherence and the volvulus Dr. INGERSOLL, will you describe the course following operation?

DR. INGERSOLL The patient was an elderly woman, and we were pleased for the next ten days that the progress was satisfactory During that time she passed a little gas and had a moderate amount of drainage from the nasal tube, and we thought that she was over the worst part of the illness On the eighth and ninth days, however, she was nauseated and passed gas and watery movements by rectum On the eleventh day she was again nauseated Physical examination revealed active peristalsis, but there was a mass in the right upper quadrant This mass seemed to be connected with the liver It was quite discrete and very easy to feel There was no spasm except over the mass, and the rest of the abdomen was soft and non-tender She was jaundiced It was apparent that she was a desperately ill woman, and that nothing further surgically could be done at that time She was given supportive therapy and had a shaking chill in the afternoon and another in the evening At 4 in the afternoon she was quite deeply jaundiced, and the pulse, which had been 88 in the morning, was 130, and the temperature was 105°F The house officers were called late that night and said that she was more deeply jaundiced than she had been at 6 or 7 in the evening, when I had seen her She died early in the morning

DR. CASTLEMAN Autopsy showed an acute condition of the gall bladder, which was distended, markedly injected and covered with fibrin A small stone, 1 cm above the ampulla of Vater in the common bile duct, was completely obstructing the lumen No other stones were found in the bile ducts or gall bladder The liver was enlarged and deep green

CASE 33452

PRESENTATION OF CASE

A seventy-two-year-old Negro entered the hospital because of swelling in the neck

Seven months before admission a swelling in the neck had been noted in the Out Patient Department of a neighboring hospital, and since that time the patient had observed that it did not change

appreciably in size. There had been no difficulty in breathing or swallowing and no toxic symptoms. He had lost 30 pounds in weight during the year prior to admission. Scoliosis of the spine had been present all his life and had become somewhat worse during the few years prior to admission. Twenty-one years before admission cough, weakness, weight loss and chest pain were noted, and a diagnosis of tuberculosis was made. Treatment consisted of rest at home, and apparent recovery ensued. There had been no hemoptysis and no recent cough. During the two months before admission he had been bothered by dyspnea and left precordial pain on exertion. There was no ankle swelling.

The patient admitted to having had gonorrhea in his youth and during the three years before admission suffered from urinary hesitancy and a weak stream. A year after the onset of these complaints a sinus appeared in the perineum, which drained pus but never urine or fecal material. This never actually bothered him until three months before admission, when he noted the onset of frequency of urination associated with considerable perineal pain. There was also pain on moving the bowels. For two weeks before admission he had been bothered by marked anorexia and occasional attacks of "dry heaves." He admitted to having always liked cabbage and to having eaten much of it all his life.

Physical examination showed a well developed but emaciated man. The thyroid gland was diffusely enlarged to about four times the normal size, moderately firm and nontender. No bruit was heard. The spine showed moderate scoliosis, with convexity to the right in the dorsal region and to the left in the lumbar region. There were dullness, decreased breath sounds and tubular breathing over the left apex and a high diaphragm without movement on the left side. Over the right apex the breath sounds had a tubular quality, and whispered voice was increased. The heart was enlarged to percussion, the sounds were of fair quality, and there were occasional premature beats with compensatory pause and no pulse deficit but notable variation in force of beat. No murmurs were heard. There was moderate costovertebral-angle tenderness. The right testicle was atrophic, and the cord was thickened. There was a sinus at the perineoscrotal angle. Rectal examination was unsatisfactory because of extreme generalized tenderness.

The temperature was 99°F, the pulse 80, and the respirations 20. The blood pressure was 120 systolic, 70 diastolic.

The urine showed a +++ test for albumin and contained innumerable white cells. The hemoglobin was 98 gm per 100 cc, and the white-cell count 19,500, with 81 per cent neutrophils. The non-protein nitrogen was 70 mg per 100 cc. A smear from the perineal sinus was negative for acid-fast bacilli. Urine cultures revealed abundant colon

bacilli and nonhemolytic streptococci. Smears showed no tubercle bacilli.

An x-ray film of the chest disclosed marked kyphoscoliosis. The left leaf of the diaphragm and the left border of the heart could not be traced, and only a few cystic areas of lung could be seen on the left side. The right lung showed mottled areas of increased density scattered throughout all lung fields, particularly at the apex. The hospital course was febrile, with temperatures as high as 102.5°F and with white-cell counts as high as 38,000. Catheterization revealed 3000 cc of residual urine, the urethra was dilated, and a Foley catheter inserted. Digital examination on the third hospital day ruptured a perirectal abscess into the rectum. On the fifth hospital day the patient was found to be cold, clammy and unresponsive. The pulse was 130, the respirations 40 and grunting, and the blood pressure 80 systolic, 20 diastolic. He died later on the same day.

DIFFERENTIAL DIAGNOSIS

DR EARLE M. CHAPMAN: May we see the x-ray films?

DR STANLEY M. WYMAN: It is impossible to outline the left leaf of the diaphragm. I cannot describe the heart, which is inadequately defined. The left side of the chest contains numerous, rather thick-walled, cyst-like areas, with no obvious fluid in the rounded areas. The possibility of a herniation of colon into the chest might be mentioned in passing. I do not consider that very likely, however. This is the scoliotic spine, with kyphosis also apparent in the lateral view. Throughout the right lung there is mottled density, which is rather concentrated at the apex. The density is somewhat linear but also rather soft and mottled in the lower two thirds of the lung field. I believe that this is old chronic disease in the left side of the chest. What is going on in the right side is hard to say.

DR CHAPMAN: Does it look like active tuberculosis to you?

DR WYMAN: It might be a bronchial spread or, less likely, a miliary spread of tuberculosis, although it does not look typical of the latter. I do not see cavity formation, but cavities might be concealed in the right apex.

DR CHAPMAN: The physical findings were suggestive of cavitation.

DR WYMAN: In this view the rarefaction can be seen. It could be cavitation.

DR CHAPMAN: Do you think that that is cystic disease of the lung on the left?

DR WYMAN: Yes, it might be due to a sclerosing process, possibly tuberculous, with bronchial involvement.

DR CHAPMAN: The mechanical factor compressing the left lung must be considered. We know that patients with severe scoliosis sometimes de-

velop emphysematous blebs as an attempt at compensation

DR WYMAN I think that this is more than emphysema. These are thick-walled, cyst-like areas in the lung, not thin-walled emphysematous blebs. Perhaps in keeping with that is the suggestion of thickening of the pleura along the lateral chest wall.

DR CHAPMAN It is not surprising that there was severe dyspnea. Evidently, the vital capacity was not determined, but I assume that it was markedly reduced. This man had known tuberculosis, and toward the end he must have had bilateral extensive tuberculosis with cavitation and with perhaps more recent spread on the right. An interesting clinical point in patients with this degree of tuberculosis is that they have dyspnea out of proportion to the signs on examination. The history is compatible with that diagnosis, but there was something else going on—that is, a perirectal abscess, which was drained. In addition, the urine contained a great deal of albumin, and there were signs of uremia. The question arises, Was this on an obstructive basis from the perirectal abscess, or, in the face of this long-standing disease, did the patient have amyloid disease of the kidney? Little or nothing about renal function is indicated. It is stated that there was tenderness in the costo-vertebral angle and retention of urine, with 300 cc of residual urine, and that the patient was in uremia. I do not see how it is possible to establish which of these two possibilities was present, but we must consider the possibility of amyloid disease of the kidney.

Then we come to the matter of thyroid disease, because of this mass in the neck, and I assume that that is why I was asked to discuss this case. The patient first came to the hospital because of swelling of the neck, and a goiter could be felt that was about four times the size of a normal thyroid gland and was moderately firm and nontender.

I wondered about thyroid hyperplasia, but there is no evidence in this record of symptoms or signs of hyperthyroidism, so that we can exclude that diagnosis. With all this tuberculosis in the body,—at least I assume it to have been that,—was this tuberculosis of the thyroid gland? That is extremely rare. It does happen, but tuberculosis in a gland as vascular as the thyroid is rare indeed. I doubt if we have ever seen a case in this hospital, although it has been reported. I have never seen a case, and I recall a recent case at the Baker Memorial with a hard nodular mass and the signs of tuberculosis in which Dr Donaldson operated, thinking that it was tuberculosis of the thyroid gland. They were tuberculous nodes densely adherent to the gland but not invading it. Is that correct, Dr Donaldson?

DR GORDON A DONALDSON That is my recollection.

DR CHAPMAN Another important point is that the mass was nontender. Tuberculous thyroiditis would produce signs of inflammation that would have been evident on physical examination.

Could this have been amyloid disease of the kidney and the thyroid gland? One must consider amyloid in the thyroid gland. I had not been aware of that diagnosis until a case was discussed at Grand Rounds a few months ago of a man with rheumatoid arthritis, who had such a mass, which histologically proved to be amyloid. One must therefore keep that possibility in mind, but another case in the same year would be a great rarity. Simply on the law of chances, I should say that it was not amyloid.

Since this man liked cabbage, which is one of the common goitrogens because of its content of cyanate ion, we come to the most likely possibility—that is, an iodine-deficiency goiter. Astwood¹ and the VanderLaans² have recently explained the mechanism by which this occurs. Another possibility is a type of thyroiditis known as Hashimoto struma. In some cases of the Hashimoto type giant-cell formation simulating tuberculosis has been described. If Dr Mallory says that there were giant cells I can still say that does not prove the disease to have been tuberculosis. So much for the differential diagnostic points concerning the thyroid gland.

Then we come to the final episode. Why did this man die so abruptly? I am sure that I do not know. There are two or three things that come to mind. He was doing fairly well until he suffered the shock of rupture of the perirectal abscess. If he did not die from the shock of that, he might have had sepsis from it. He had kyphosis, the heart was enlarged, and he had premature beats, and irritability of the heart, suggesting that the myocardium was not a very healthy one. As a terminal episode he may have had severe heart failure or cardiac infarction. I see no way of making the diagnosis.

In conclusion, I shall say that he had tuberculosis, bilateral and extensive, with cavitation, perirectal abscess, questionable prostatic tuberculosis and questionable amyloid kidney with uremia, and that in my judgment this was an iodine-deficient goiter induced by goitrogens and not hyperplasia, or amyloid disease, tuberculosis or Hashimoto struma.

DR CHARLES E RICHARDS I wonder why Dr Chapman has not mentioned carcinoma in the differential diagnosis.

DR CHAPMAN There is no mention of the gland's being fixed. It seemed unlikely that it would be carcinoma, but I suppose that I could have included that diagnosis to be encyclopedic.

DR DONALD S KING I think that he had active tuberculosis, but I wonder if one could prove it. I should have to guess that he had it, but I am not absolutely certain.

DR TRACY B MALLORY I almost hesitate to admit that this patient was in the hospital for five days and that no sputum examination was ever made

PROFESSOR HERMAN SIKL Perhaps blockage of the bronchus produced fibrosis of the lungs

DR HELEN S PITTMAN When I first saw this man he was in the Out Patient Department, and I had no idea what was the matter basically. Obviously, he had an enormous thyroid gland—not hard or tender and not fixed, but causing some pressure. I thought that he had Pott's disease and a tuberculous draining abscess, secondary to that, and was quite sure that he had old pulmonary tuberculosis and arteriosclerotic heart disease

DR CHAPMAN That is helpful, and it makes me think more of carcinoma, as Dr Richards brought out. I thought that this was a stationary lesion. As you describe it, it makes one think of carcinoma simplex, a rapidly spreading type. The man was not very observant, and the thyroid gland seems to have been growing much faster than one would gather from the history

DR PITTMAN The patient was not a careful observer, but our impression was that the gland was growing rapidly

CLINICAL DIAGNOSES

Adenoma, nontoxic, of thyroid gland
Tuberculosis of vertebrae
Perirectal abscess and prostatitis

DR CHAPMAN'S DIAGNOSES

Tuberculosis, bilateral, extensive, with cavitation.
Perirectal abscess
Prostatic tuberculosis?
Amyloid kidney(?), with uremia
Iodine-deficient goiter (cyanate)

ANATOMICAL DIAGNOSES

Pulmonary tuberculosis, chronic
Bronchiectasis
Cor pulmonale, slight
Tuberculosis of prostate gland, seminal vesicles and epididymis, active
Amyloid goiter
Amyloid nephrosis, slight

PATHOLOGICAL DISCUSSION

DR MALLORY The heart did not show any coronary disease. It was slightly hypertrophied, particularly the right ventricle, justifying the diagnosis of cor pulmonale. This is not uncommon in kyphoscoliosis, but there was also severe pulmonary disease. The pulmonary picture was very complicated. There was extensive old tuberculosis, but it was mostly fibrous, with encapsulated caseous foci, and relatively inactive. The cavities that Dr. Wyman demonstrated were greatly dilated bronchi, which, at the time of autopsy, were filled with purulent secretions. I believe that bronchiectasis was perhaps the most important factor in the patient's death. The vertebral column was, of course, greatly twisted, as the x-ray films show, but there were no collapsed vertebrae that would permit a diagnosis of Pott's disease. The most active tuberculosis found was in the lower urinary tract. The prostate, seminal vesicles and right epididymis all showed involvement.

Our interest naturally centers around the thyroid gland, which showed parenchymal atrophy, great numbers of fat cells and masses of homogeneous material that had the staining reactions of amyloid. This makes the second amyloid goiter in a short time. Amyloid is a rare disease in this area. These are the only 2 cases of amyloid goiter that I have seen. Perhaps Professor Sikl is more familiar with them in his material in Prague.

PROFESSOR SIKL No

DR LOUIS K DAHL Was there any amyloid anywhere else in the body?

DR MALLORY Traces were present in the kidneys but not in the spleen, the liver or the adrenal glands—the other usual foci.

DR ALLAN G BRAILEY Is it apparent why the patient died?

DR MALLORY We have no explanation why he died or when he died. Patients with scoliosis are very prone to sudden cardiac death without any warning or premonitory signs. He had, in addition, active tuberculosis and severe bronchiectasis. Perhaps, as Dr. Chapman suggests, the rupture of the perirectal abscess was enough to tip the balance.

A WARNING REGARDING THE USE OF FOLIC ACID

An alarming incidence has been reported of neurologic relapse or progression of pre-existing neurologic lesions in cases of pernicious anemia treated with folic acid, the term being used to indicate synthetic pteroylglutamic acid. Sargent's review, presented elsewhere in this issue of the *Journal*, places the incidence of such neurologic lesions at about 20 per cent during a period of one year or less of therapy. More recent studies show an even higher rate. Ross¹ observed an incidence of over 50 per cent in 21 cases. In Wagley's² series of 10 cases, 8 developed neurologic lesions or progression of pre-existing lesions within eight days to twelve months after the institution of folic acid therapy. Two cases of sprue have been noted in which neurologic

lesions occurred during folic acid therapy.³ In one of these cases, the lesions recurred during a second course of folic acid therapy. These figures are obviously in striking contrast to the well known results with therapy by liver extract or gastric preparations, which in adequate dosage almost invariably arrest existing neurologic lesions or prevent the subsequent development of nerve changes. Indeed, these findings suggest that substitution of the newer remedy places the patient's continued health in jeopardy.

In most of the cases treated with folic acid the patients were subjectively in good health, and the red-cell count and hemoglobin had returned to normal levels at the time that the neurologic signs appeared. Increasing the dosage of folic acid nevertheless failed to prevent progress of the neurologic lesions. These have occurred in cases receiving as much as 500 mg daily, or about twenty-five times the average amount required for the relief of the hematologic abnormalities. It appears, therefore, that the neurologic changes cannot be ascribed to inadequate folic acid dosage.

Three possible relations of folic acid to the neurologic disturbances exist. First, folic acid may merely be allowing the disease to run its natural course so far as the nervous system is concerned. This may actually have happened in some of the reported cases. In contrast to the neurologic signs in combined system disease, however, few cases have shown unequivocal evidence of lateral column involvement, despite severe and extensive posterior column disturbance. Secondly, Heinle and Welch⁴ have suggested that folic acid in relieving one deficiency accentuates another, which is in turn responsible for the neurologic changes, as occurs occasionally with other members of the vitamin B complex. Thus, cure of pellagra by nicotinic acid may result in manifest thiamine deficiency. The third explanation is that folic acid may actually exert a positively deleterious influence on the nervous system. Thus, by some close chemical relation to substances required to maintain the integrity of the nervous system, folic acid may competitively interfere with the nutrition of the spinal cord just as certain vitamin deficiencies in experimental animals may be caused by closely related chemicals.

Thiamine deficiency, for example, may be induced by the administration of pyriethamine, and pantothenic acid deficiency by pantoyletaurine. Ross³ has recently suggested that pteroylglutamic acid may interfere with the metabolism of glutamic acid by the central nervous system, which, according to a preliminary observation by Pearson,⁶ it appears to do, at least in vitro.

A positively injurious effect of folic acid therapy is consistent with the following features of the neurologic disturbance. In many cases an explosive onset and spread of the neurologic lesion has been noted. On the other hand, whereas combined system disease may start acutely, it does so only rarely. Several cases have been reported in which liver extract had been taken sporadically and in amounts inadequate to maintain normal blood levels for periods as long as ten years, without the development of nerve lesions. Yet on changing to folic acid therapy the sudden onset of severe neurologic manifestations occurred within a few weeks.⁶ Ross¹ observed 1 case in which the addition of liver-extract therapy produced little if any improvement in the neurologic picture until folic acid administration was stopped. Indeed, the usual improvement in neurologic function occurring on withdrawal of folic acid and the institution of liver-extract therapy may be ascribed as much to the removal of the causative factor as to a response to the liver extract. Thus, giving liver extract with folic acid may not guarantee that neurologic disturbances will not develop. A further suggestion of a toxic action of folic acid is that the incidence of neurologic changes during folic acid therapy appears to parallel to some extent the dosage and frequency of administration. In cases treated with large daily doses of 25 to 50 mg the incidence has been highest, whereas in a series receiving only 75 mg once a week, the incidence was but 1 out of 11 cases. A possible explanation is that a large portion of a single dose is lost in the urine within twenty-four hours and that consequently with weekly administration the nervous system is exposed to very little folic acid in the intervening six days.

The inadequacy of folic acid in the treatment of pernicious anemia is also noted in the incidence of glossitis with such therapy. In Hall's⁷ series 7 pa-

tients showed glossitis before commencement of therapy. Three improved temporarily and then relapsed, and 1 became worse. In Wagley's² series, 2 patients developed glossitis for the first time while on folic acid therapy, and another showed marked increase in the soreness of the tongue and developed glossal petechiae. Such developments are virtually unknown with adequate therapy by liver or stomach preparations.

Pteroylglutamic acid is the first hematopoietic substance in pernicious anemia to be chemically identified. When it became available in pure synthetic form about two years ago, it appeared likely to replace the older empirical but highly effective preparations of liver or stomach. Now, however, sufficient evidence has accumulated to justify a warning that synthetic pteroylglutamic acid (folic acid) should not be used in the treatment of pernicious anemia. In view of the reports of folic-acid-induced neurologic lesions in sprue,³ this restriction should probably apply also to other nutritional macrocytic anemias. Folic acid has failed to be effective in other conditions in which liver or stomach preparations have also failed to benefit the patient. Consequently the use of folic acid as a therapeutic agent appears to offer no new benefit but only risk to the patient.

EPIDEMIC LEAD POISONING

It is close to a century since the medical profession began to warn the public of the danger of lead poisoning. They did it poetically in those days, too, Dr. Samuel L. Dana, of Newton, told the city officials of Lowell, "It is found by experience that the young, the delicate, soonest succumb under the effects of lead drank in their daily drink, and like

the dew of heaven, descending on all, the gentlest and fairest feel the chill which soon closes in death."

In recent years the public has been amply warned of the lead hazards by which it may be surrounded. Emphasis has sometimes been mistakenly placed by the medical profession, as when it warned against lead painted toys and children's cribs only to find that none of the toy or crib manufacturers used lead in their paints. The vast expansion in the use of lead by modern civilization, however, makes a far wider field for exposure than that produced by painted surfaces, even including those painted with the brand that is reputed to "cover the world."

Approximately a million tons of lead are used each year in the United States. Symptoms from the absorption of this metal are now almost wholly confined to those who are exposed in industry. The largest single user of lead is the storage-battery industry, and although poisoning may and does occur in this and other industries, it is, on the whole, well controlled. In nonindustrial life it is only under peculiar and unusual circumstances that lead poisoning appears, but several epidemics, which extend back to 1933, have been recorded that seem to be difficult to approach from the point of view of public education. These epidemics were due to the use of discarded storage-battery casings for fuel. The casings burn readily but are enervated with lead salts, which become volatilized in the smoke and fumes. When such fumes escape through a leaky stove they can readily poison a whole family. The most recent account of this sort of epidemic appeared in an article by Cooper³ in which an outbreak in Staunton, Virginia, is described. Health authorities discovered that war-time scarcity of fuel had led a whole neighborhood into the habit of burning discarded battery casings, with the result that 17 children were found to have latent or toxic lead poisoning. It is interesting to note that Dr. Cooper agrees with Dr. Dana, quoted above, for he writes concerning one aspect of the subject, "In epidemics of lead poisoning in which both children and adults have been exposed in the same manner and amount, children are uniformly found to be more susceptible, particularly those under four years of age."

With the coming of colder weather, and with the continuation of a fuel supply that is neither abundant

nor cheap, a word of warning regarding this possible source of lead poisoning may be appropriately placed in the minds of physicians, public-health officials and even legislators, for there could be a law to regulate the disposal of discarded battery casings—many less rational laws have been enacted.

MASSACHUSETTS MEDICAL SOCIETY BUREAU OF CLINICAL INFORMATION

All secretaries of various medical groups, such as special societies and alumni associations, are requested to notify the Bureau of Clinical Information regarding scheduled meetings, annual dinners and so forth. If such data are on file, it is hoped that duplication of dates can be avoided.

APPOINTMENT OF DR. H. QUIMBY GALLUPE

Dr. H. Quimby Gallupe of Waltham, has been appointed by the president of the Massachusetts Medical Society secretary *pro tempore* to complete the unexpired term of Dr. Joseph Garland, who resigned to assume the editorship of the *New England Journal of Medicine*. Dr. Gallupe's appointment dates from November 1, 1947, when his predecessor's resignation became effective.

Dr. Gallupe is well known to the members of the Society for the exceptional efficiency with which he has performed his duties as secretary of the Massachusetts Board of Registration in Medicine over a period of nearly six years, and for his authorship of the Gallupe Plan, first put into operation at the Waltham Hospital two years ago.

The new secretary graduated from Tufts College in 1911 and from Harvard Medical School in 1918. He is surgeon-in-chief of the Waltham Hospital. In addition to his position as secretary of the Board of Registration in Medicine he is secretary of the Board of Registration in Nursing, chairman of the Approving Authority for Medical Schools and secretary of the Approving Authority for Nursing Schools. In the Massachusetts Medical Society he has served long as councilor from the Middlesex South District and, in addition, has been chairman of the Committee on Arrangements, chairman of the Committee on Membership and Finance and supervising censor.

His broad experience should be a distinct asset to the Society.

A HUNDRED YEARS AGO

Dr Henry J Bigelow reports the unusual case of Jane McMurphy of Derry, New Hampshire. She is 17, small in stature, and of healthy appearance. Five years ago a piece of tobacco was inserted in her right ear by an old woman for earache. Of the piece of tobacco the patient saw no more at the time, but at the end of a month and for the subsequent months a physician succeeded in removing a portion of what was said to be tobacco, and at the end of a year two more fragments were extracted. In March 1846, the patient while lying in bed first heard a noise. It commenced suddenly and since then it has continued with little intermission. A person sitting in the room with this patient, hears a distant muffled sound, which might easily be mistaken for the rapid dropping of water into the bowl of a closed washstand. The sound may be conveyed by the words *click click*, or occasionally *click-click*, *click-click*, etc. The patient being requested to open her mouth, the sound becomes surprisingly distinct and audible, all the beats being apparently stimulated by the effort or by the contact of the air and the ticking becomes rapid. There is no discoverable discharge of pus or blood. The sound may be in an alternate opening and closure of the moist mouth of a sac, by which a bubble of air is expelled at each contraction, and a bubble sucked in at each dilation of its cavity. Such a sac exists between the vocal cords, or might be formed at one extremity of the os hyoides, with a fistulous opening. Such a solution of the cause of this singular sound is far from satisfactory, yet it is difficult to adduce any additional evidence of its nature. During her residence in the Hospital, Dr B deemed it unnecessary to harass the patient by repeating applications which seemed to have been faithfully tried, and the patient was altogether unwilling to submit to the division of one of the pillars of the palate which he proposed to her. — From a recent conversation with a medical practitioner belonging to the State of Tennessee, we learned the novel fact that a decided advantage is realized by consumptive patients in the middle and southern states in going North instead of South. Here the opinion is universal that persons with irritable lungs and more especially such as have a decided tendency to phthisis should go somewhere South. Without contending with anyone on the doctrines of contraries, as going South from the North, and North from the South, to allay symptoms and tendencies similar in character, we prefer that those most familiar with the results of such practice should discuss the subject — and whatever light may be exhibited, if it is truly light, will be received by us and the pro-

fession with feelings of gratitude. — At Meredith Bridge, N H, Mr B F Palmer carries on the manufacture of artificial limbs to a degree of perfection that both astonishes and delights all who have examined his ingenious life-like looking workmanship. Should the Mexican war continue much longer, the demand upon Mr Palmer's establishment must actively increase. — Dr Channing, having been Dean of the Medical Faculty of Harvard College for twenty-two years, has resigned the office, and Dr Holmes has been appointed in his place. — H K, a farmer, aged about 45, stout and healthy, of sanguine temperament, much addicted to inebriety, and very quarrelsome while under the influence of liquor, on August 19th, 1840, while intoxicated, undertook to chastise a small man. The latter, not feeling a disposition to submit to a drubbing, shot Mr K with a shot-gun loaded with shot and tow wadding, the muzzle of the gun being in contact with the left side of the epigastric region. Mr K fell, as if dead, and was conveyed home by four men in a sheet. On medical examination there was a large opening in the left side, as broad as a man's hand and about as long, indeed it looked as if his whole side had been torn away. He was immediately given a little of his favorite beverage, to wit, brandy and water, and bottles of hot water were applied to the axillae and between the thighs. On further examination it was found that the seventh and eighth ribs had been torn off from the attachment at the sternum to within three inches of the spine, together with all their appurtenances, the pleura included — thus exposing the lungs, diaphragm, stomach and pericardium! Most of the wadding was removed, and some of the fragments of the missing ribs. In the course of time Mr K recovered his former health and strength, he also returned to his former habit of dissipation and has had many a pugilistic contest since. In consequence of the loss of two ribs, he leans considerably to the left side. The case presents several points of interest. Here was a man with almost half of his left side torn off, thus admitting a free current of air not only into the pleura, but lungs and whole cavity of the chest. He survived contrary to the teaching that it is death for air to penetrate through the thoracic parietes, and contrary to the aphorism of Hunter, "that those who always live above par are extremely liable to sink when attacked by disease or injury." He felt no inconvenience nor unpleasant consequences despite the presence of a silver tube which he was forced to wear for several months to drain the pleural cavity. — Extracted from the *Boston Medical and Surgical Journal*, November 1847.

*Three-year median.
†Five-year median.

COMMENT

Diseases above the seven-year median are chicken pox, diphtheria, dog bite, lobar pneumonia, poliomyelitis and undulant fever.

Diseases below the seven year median are bacillary dysentery, German measles, gonorrhea, malaria, measles, meningococcal meningitis, mumps, salmonellosis, scarlet fever, syphilis, pulmonary tuberculosis, tuberculosis (other forms), typhoid fever and whooping cough.

Diphtheria incidence is continuing the seasonal decline—17 cases compared to 20 in July. The trend will undoubtedly reverse early in the fall.

Poliomyelitis has increased from 21 cases in July to 80 this month. The seven year median incidence is 45. The disease will probably show an early seasonal peak in contrast to the late peak in 1946.

This is the first month in which no cases of meningococcal meningitis were reported since 1940.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Boston 9, Canton 1, Chelsea, 1, Medford, 2, Melrose 1; Revere, 2, Sangus, 1, total, 17.

Dysentery, amebic, was reported from Boston, 1, total 1. Dysentery, bacillary, was reported from Beverly 1, Boston, 2, Cambridge, 1, Gloucester 1, Lawrence 1, Worcester, 3, total, 9.

Lymphocytic choriomeningitis was reported from Pittsfield, 1, total, 1.

Malaria was reported from Boston 3, Lynn, 2, Manchester, 1, Newton 1, total, 7.

Meningitis Pfeiffer bacillus was reported from Worcester 1; total 1.

Meningitis, streptococcal, was reported from Norwood, 1, total, 1.

Meningitis, other forms, was reported from Brookline, 1; total, 1.

Meningitis, undetermined was reported from: Dracut, 1, Haverhill, 1, Springfield, 1, total 3.

Poliomyelitis was reported from Andover, 1, Arlington, 2, Attleboro 1, Beverly, 2, Boston 9, Brockton 1; Cambridge, 6; Carleton 2, Dighton 1, Fairhaven 2, Falmouth 1, Fall River, 5, Franklin, 1, Freetown, 1, Great Barrington, 1, Hull, 1; Ipswich, 1, Lenox, 1, Lowell, 1, Lynn, 1, Middleboro, 1, Milford, 1, Milton, 1, New Bedford, 3, New Marlboro, 1, Newton, 4, North Attleboro 2, Northampton 1;

Northfield, 1, Pittsfield, 2, Revere, 1, Salem, 3, Somerville, 2; Southbridge, 1, Stoneham, 1, Taunton, 4, Waltham, 1, West Stockbridge, 1, Weston, 1, Westwood, 2, Winthrop 2, Worcester, 3, total, 80.

Salmonellosis was reported from Beverly, 2, Boston 2, Cambridge, 1, Chatham, 1, Lowell, 1, Monterey 2, Natick, 1, New Bedford, 1, Newton 1, Salem 1, Taunton, 1, Waltham 1, Watertown 2, Winchester, 1, Worcester, 1, total, 19.

Trachoma was reported from Boston 1, total, 1.

Trichinosis was reported from Boston 1, Fall River, 1, Pittsfield, 1, Springfield 1, Stoneham, 1, total, 5.

Tularemia was reported from Duxbury 1, Warcham, 1, total, 2.

Typhoid fever was reported from Boston 1, Grafton 1, total, 2.

Undulant fever was reported from Boston, 1, Chicopee, 1, Gardner, 1, Haverhill, 1, Holyoke, 1, Lexington, 1, Melrose, 1, total, 7.

MISCELLANY

NOTE

Dr. Erich Lindemann, formerly associate in psychiatry at Harvard Medical School, was recently appointed to the Harvard University Faculty of Arts and Sciences to broaden the scope of the new Department of Social Relations. He will continue as a member of the staff of Massachusetts General Hospital. Dr. Lindemann will concern himself with the study of psychologic disturbances of the individual, with special reference to the role of his social relations as a cause of disturbance and as a source of therapeutic aid. His courses will include dynamic psychology and clinical problems in psychology medicine. In joining the Department of Social Relations which was established last year, Dr. Lindemann will associate himself with sociologists, psychologists and anthropologists. The new Department was formed to break down the limitations of individual departments in working on common problems of social relations.

Dr. Lindemann's research has included experiments in the use of narcoanalysis in treating mental disorders and an original study of the psychiatry of grief, which followed the Coconut Grove fire in Boston.

Dr. Lindemann received his Ph.D. degree in Psychology from Marburg University in 1922 and his M.D. degree from Cologne University in 1926. He came to the United States in 1927. He was a research fellow at Iowa State University from 1927 to 1929, afterward serving as instructor in psychology and psychiatry (1929-1931), assistant professor of psychiatry (1931-1935), and assistant professor of psychology (1932-1935). He was research fellow in neurology and psychiatry at the Harvard Medical School from 1935 to 1937 and was instructor in psychiatry (1937-1941) and associate in psychiatry from 1941 until his present appointment. He also served as instructor in psychiatry, Harvard School of Public Health.

Hospital positions held by Dr. Lindemann include assistant psychiatrist and chief, Psychiatric Out Patient Department, Iowa Psychopathic Hospital (1931-1935), student mental hygiene adviser (1933-1935), associate psychiatrist (1937) and psychiatrist (1943), Massachusetts General Hospital, physician-in-charge, Psychiatric Out Patient Department (1937) and consulting psychiatrist, Massachusetts Eye and Ear Infirmary (1941).

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

NOTICES

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES

The annual meeting of the Association of Military Surgeons of the United States will be held at the Hotel Statler, Boston, from November 13 to 15, inclusive. An unusual program is being offered, with special emphasis on many interesting features developed during the war and since V-J day. Technical information and findings not hitherto generally published will be released by high-ranking representatives of the Army, Navy and Air Force. Speakers from the United States Public Health Service and the Veterans Administration will also participate in this meeting.

All interested physicians are invited.

BOSTON SOCIETY OF PSYCHIATRY AND NEUROLOGY

A joint meeting of the Boston Society of Psychiatry and Neurology and the New England Pathological Society will be held at the Boston Medical Library, 8 Fenway, Boston, on Thursday, November 20, at 8 15 Dr J W Kernohan will speak on "Secondary Changes Produced by Expanding Intracranial Lesions."

MEDICAL GROUP PRACTICE IN THE UNITED STATES*

II Survey of Five Groups in New England and the Middle Atlantic States

G. HALSEY HUNT, M.D.,† AND MARCUS GOLDSTEIN, Ph.D.‡

THIS is the second of a series of reports on the purposes and findings of a study of medical group practice conducted by the United States Public Health Service.

During the first eight months of 1946, techniques for the study of group-practice units were worked out and tested in studies of five groups in New England and the Middle Atlantic states. The general method of study, outlined in the first paper of this series,¹ involves approaches by two techniques: an intensive interview survey of the physicians and key administrative personnel of the group, and a statistical analysis of a random sample of the group's medical records. The present paper is concerned only with the development, application and results of the interview survey. Studies are being continued in other parts of the country, and will be the subject of future reports.

METHOD OF STUDY

For the study of the first group, comprehensive interview outlines were worked out to obtain detailed information about the group's professional and administrative practices, facilities and personnel, including biographical data on the individual members, and to carry out an opinion survey of the physicians. Interview outlines previously used by Roberts² were rearranged and amplified to form the basis of the schedules dealing with the practices of the group as a whole. After the first study, the schedules were revised somewhat and were used for two other groups. Further revision was then found to be necessary, and the resulting schedules were employed with the last two groups. No other major revisions are contemplated for the duration of this study. In the present report, comparable data for all five groups have been used, unless a specific note to the contrary has been made.

The study can of course be conducted only with the full permission and co-operation of the group being studied. The interview survey is carried out

by an analyst familiar with medical practices, who spends two or three weeks with each group. Information regarding administrative and fiscal practices, personnel and facilities are obtained by the analyst from the principal medical and nonmedical administrators of the group. An effort is made to interview each physician and to obtain his opinions on group practice, as well as details of his training and experience.

Because of the lack of factual knowledge about groups and group practice generally, the interview outlines go into considerable detail concerning all aspects of the personnel, organization and practices of groups, consideration of the incomes of individual physicians alone being omitted. It is hoped that by analysis of this mass of detailed information, the common patterns and the variations of organization and practices may be determined.

The data given below, which were selected from the available material either on the basis of known or assumed intrinsic importance or on that of variation among the five groups studied, are primarily presented as illustrations of the kind of information sought in the study and are not necessarily indicative of the nature of group practice in general. The findings are discussed under the following headings: organization, facilities, scope and type of services, professional standards, financial arrangements, volume of work in 1945 and opinion.

ORGANIZATION

The great majority of medical groups in the United States are private partnerships, but there are also substantial numbers of hospital groups, industrial groups and consumer-sponsored groups. The classes considered in this report fall into three of these four categories. No consumer-sponsored group was studied in the New England and Middle Atlantic States. Two of the groups are private partnerships, two are hospital groups, with ownership and authority vested in a nonprofit community hospital, and one is an industrial group, with ownership and authority vested in an industrial company. In the last group, the employees and their

*From the Division of Public Health Methods, United States Public Health Service.

†Senior Surgeon, United States Public Health Service.

‡Public health administrator.

dependents make up the total patient load. All five groups have existed for many years, the period of existence as groups ranging from seventeen to thirty years.

FACILITIES

The study schedules go into detail about the physical facilities, equipment and hospitals used by each group, but in view of the small number of groups in this series, discussion is limited to a brief consideration of the offices and hospital facilities.

Offices Each of the two hospital groups has its offices in the hospital building. One of the partnership groups owns its building, and the other has transferred its clinic-building title to the hospital with which it is integrally affiliated. The industrial group uses two main buildings and two annexes, all owned by the company and located in the adjacent cities in which the company has its plants.

Hospital facilities The members of the hospital groups make up the complete staffs of their respective hospitals. Of the two private partnership groups, one is integrally affiliated with a hospital and comprises its complete staff, whereas members of the other group are on the staff of a local community hospital but do not control its professional policies. The industrial group is closely associated with a community hospital with which all its full-time members have staff affiliations, the group controls to a large extent the professional policies of the hospital.

The hospitals range in size from 95 to 374 beds. All the hospitals are registered with the American Medical Association, and all are approved by the American College of Surgeons. Four of the five are approved for intern and resident training by the American Medical Association.

SCOPE AND TYPE OF SERVICES

The scope and type of services offered by a group are related to its size, the fields of medicine covered by its staff, the variety of ancillary services furnished, the medical requirements of the group's clientele and, possibly most important, the orientation of the group toward either general medical care or specialized work for referred patients.

Primary Activity

A classification of medical groups according to the type of medical services offered was presented in the introductory paper.¹ A service group is one in which the principal activity is the furnishing of complete medical care to a continuing clientele, whereas a reference group primarily furnishes specialized care to patients referred to them by outside physicians, usually for a single episode of illness. According to this classification, three of the present groups (one private, one hospital and one industrial) are service groups, and two (one private and one hospital) are reference groups. It was noted in the

previous paper that this classification is not absolute, but merely serves to define the principal function of the group. A mixture of activity was found in all the present groups except the industrial group, which is purely service in type. The other two service groups, especially the hospital service group, do a certain amount of referred work, and the two reference groups furnish a certain amount of general medical care. It may be pointed out again that a service group may be composed entirely of specialists. The distinction between service and reference groups is based on a determination of whether the group *as a group* is primarily acting as a "general practitioner" or as a "specialist."

Size of Groups and Fields of Medicine Covered

The five groups range in size from 15 to 46 members and are therefore larger than most groups in the United States.* Of the 122 members, 24 per cent are on a part-time basis. More than four fifths of these are in the industrial group. (Over half the membership of this group is part-time, it should be noted that the group classifies a number of men as part-time because they have the privilege of evening private practice, although they actually put in a full day's work with the group.) In the two groups providing psychiatric services, the psychiatrist is a part-time member. These figures, as well as the fields of medical practice covered by each group and the number of physicians in each field, are summarized in Table 1.

In addition to the medical services noted, all the groups provide physiotherapy, and all have clinical laboratories, although the clinical laboratories in one group are operated by the associated hospital and directed by a pathologist who is not a member of the group. Ambulance service is furnished directly only by the two hospital groups. One reference group offers oral surgery, and the industrial group provides general dentistry, including orthodontia. All the groups except one private service group have pharmacies. Only the industrial group affords specific social service.

All but one of the groups provide office, home and hospital care. The one exception, a hospital reference group, does not make home calls.

The two hospital groups have no evening or Sunday office hours for outpatients. The industrial group holds clinic hours between 8:00 a.m. and 6:00 p.m., six days a week. Both private groups have evening office hours, until 8 o'clock in one and until 9 in the other, and patients are also seen on Sunday by these two groups—regularly by one group and occasionally by the other.

An appointment schedule is rather closely adhered to in three of the groups. One of the hospital groups

*According to the report of the American Medical Association in 1940 only 5.4 per cent of groups in the United States had 15 or more physician members in 1939. A questionnaire survey conducted by the Division of Public Health Methods in the summer of 1946, a report of which is in preparation, showed that about 10 per cent of the groups now have 15 or more full-time physician members.

does not follow an appointment schedule closely, and the industrial group makes appointments only for patients seeing specialists

Communities Served

The four nonindustrial groups are located in comparatively small communities — three in places of 7000 population or less, and the other in a town of 16,000. The two reference groups draw most of their patients from within a radius of about 50 miles and thus serve estimated populations of 88,000 and 350,000 respectively. The two nonindustrial service groups draw patients from estimated populations of 65,000 and 87,000, respectively, whereas the industrial service group cares for about 50,000 employees

light on the situation. These include the age, training and experience of individual members of groups, membership in a county medical society and certification of specialists by American specialty boards and membership in recognized specialist societies. Concerning the group as a whole, consideration was given to the kind and amount of professional supervision, medical staff meetings, responsibility for patients, system of medical records employed, qualifications required of new members and requirements for postgraduate study.

Age and Years in Medical Practice

Of the 109 physicians about whom data were available, the average is forty-two and a half years of age,

and dependents, living in three contiguous cities and adjacent towns.

The two hospital groups, one reference and one service, both care for predominantly rural populations. The area served by one of the partnership groups (reference) is largely rural in character, and that of the other partnership group (service) is mainly urban and suburban. The clientele of each of the four nonindustrial groups is said to be representative of the population of the area served.

PROFESSIONAL STANDARDS

One of the obviously important questions about group practice is the professional caliber of the participating physicians. This is not susceptible of accurate measurement or of comparison with the caliber of individual practitioners, but a number of criteria have been used in an effort to throw some

light on the situation. These include the age, training and experience of individual members of groups, membership in a county medical society and certification of specialists by American specialty boards and membership in recognized specialist societies. Concerning the group as a whole, consideration was given to the kind and amount of professional supervision, medical staff meetings, responsibility for patients, system of medical records employed, qualifications required of new members and requirements for postgraduate study.

The total period of internship and residency, as well as the years in medical practice and the types of practice engaged in, is summarized in Table 2. Only physicians for whom complete information was available in these respects are included in the tabulation.

The average number of years since graduation from medical school is almost identical with Rorem's⁴ finding of an average of sixteen years since graduation for 415 physicians in 46 clinics.

dependents make up the total patient load. All five groups have existed for many years, the period of existence as groups ranging from seventeen to thirty years.

FACILITIES

The study schedules go into detail about the physical facilities, equipment and hospitals used by each group, but in view of the small number of groups in this series, discussion is limited to a brief consideration of the offices and hospital facilities.

Offices Each of the two hospital groups has its offices in the hospital building. One of the partnership groups owns its building, and the other has transferred its clinic-building title to the hospital with which it is integrally affiliated. The industrial group uses two main buildings and two annexes, all owned by the company and located in the adjacent cities in which the company has its plants.

Hospital facilities The members of the hospital groups make up the complete staffs of their respective hospitals. Of the two private partnership groups, one is integrally affiliated with a hospital and comprises its complete staff, whereas members of the other group are on the staff of a local community hospital but do not control its professional policies. The industrial group is closely associated with a community hospital with which all its full-time members have staff affiliations, the group controls to a large extent the professional policies of the hospital.

The hospitals range in size from 95 to 374 beds. All the hospitals are registered with the American Medical Association, and all are approved by the American College of Surgeons. Four of the five are approved for intern and resident training by the American Medical Association.

SCOPE AND TYPE OF SERVICES

The scope and type of services offered by a group are related to its size, the fields of medicine covered by its staff, the variety of ancillary services furnished, the medical requirements of the group's clientele and, possibly most important, the orientation of the group toward either general medical care or specialized work for referred patients.

Primary Activity

A classification of medical groups according to the type of medical services offered was presented in the introductory paper.¹ A service group is one in which the principal activity is the furnishing of complete medical care to a continuing clientele, whereas a reference group primarily furnishes specialized care to patients referred to them by outside physicians, usually for a single episode of illness. According to this classification, three of the present groups (one private, one hospital and one industrial) are service groups, and two (one private and one hospital) are reference groups. It was noted in the

previous paper that this classification is not absolute, but merely serves to define the principal function of the group. A mixture of activity was found in all the present groups except the industrial group, which is purely service in type. The other two service groups, especially the hospital service group, do a certain amount of referred work, and the two reference groups furnish a certain amount of general medical care. It may be pointed out again that a service group may be composed entirely of specialists. The distinction between service and reference groups is based on a determination of whether the group *as a group* is primarily acting as a "general practitioner" or as a "specialist."

Size of Groups and Fields of Medicine Covered

The five groups range in size from 15 to 46 members and are therefore larger than most groups in the United States.* Of the 122 members, 24 per cent are on a part-time basis. More than four fifths of these are in the industrial group. (Over half the membership of this group is part-time, it should be noted that the group classifies a number of men as part-time because they have the privilege of evening private practice, although they actually put in a full day's work with the group.) In the two groups providing psychiatric services, the psychiatrist is a part-time member. These figures, as well as the fields of medical practice covered by each group and the number of physicians in each field, are summarized in Table 1.

In addition to the medical services noted, all the groups provide physiotherapy, and all have clinical laboratories, although the clinical laboratories in one group are operated by the associated hospital and directed by a pathologist who is not a member of the group. Ambulance service is furnished directly only by the two hospital groups. One reference group offers oral surgery, and the industrial group provides general dentistry, including orthodontia. All the groups except one private service group have pharmacies. Only the industrial group affords specific social service.

All but one of the groups provide office, home and hospital care. The one exception, a hospital reference group, does not make home calls.

The two hospital groups have no evening or Sunday office hours for outpatients. The industrial group holds clinic hours between 8 00 a m and 6 00 p m, six days a week. Both private groups have evening office hours, until 8 o'clock in one and until 9 in the other, and patients are also seen on Sunday by these two groups — regularly by one group and occasionally by the other.

An appointment schedule is rather closely adhered to in three of the groups. One of the hospital groups

*According to the report of the American Medical Association in 1944, only 5.4 per cent of groups in the United States had 15 or more physicians in 1939. A questionnaire survey conducted by the Division of Public Health Methods in the summer of 1946, a report of which is in preparation, showed that about 10 per cent of the groups now have 15 or more full-time physician members.

the simplest work in any of the various specialties, becoming essentially an uncertified internist, or should he develop interest and skill in one or more specialties, becoming a partial specialist in surgery or obstetrics or some other field, with general practice as his secondary interest? These wide variations in the functions of a general practitioner, which are confusing enough in individual practice, become doubly so when an attempt is made to evaluate the place of the general practitioner in group practice.

At least four concepts are included under the term "general practitioner" as it is commonly employed, and it is important that the term be defined with sufficient accuracy for the reader to determine which concept is meant. These four concepts can be described as follows:

The physician who limits his practice to the field of internal medicine, who considers the patient as a whole individual, but who does not attempt to do any work in surgery, obstetrics or other specialized fields. As noted above, this type of "general practitioner" is essentially an uncertified internist.

The physician who treats the patient as a whole individual and who, in addition to covering the general field of internal medicine, undertakes work in surgery, obstetrics and other fields, within the limits of his training, skill, self-assurance and hospital facilities. This concept is probably most frequently in mind when the unqualified terms "general practitioner" and "old family physician" are used. It is also the kind of general practitioner who seems to be most out of place in group practice, which is usually regarded as a way of escape from the impossible task of trying to know everything about all fields of medicine.

The physician who does some work in the general field of internal medicine, who treats the patient as a whole individual but who has also developed interest and skill in an outside specialty, such as surgery. He therefore becomes a partial (often, eventually, a complete) specialist, paying less and less attention to general practice.

The physician who develops an intimate knowledge of his patients, treating them as whole individuals, but who does not attempt to treat them for any illness that falls outside his own field. This is essentially the concept of "personal physician," and can really be applied to specialists as well as to general practitioners. An eminent internist, certified in internal medicine and in gastroenterology, recently stated that he was a "general practitioner." Further discussion showed that he was using this fourth concept, and when the other concepts were outlined, he said "That sort of thing has no place in the future practice of medicine."

Precision in terminology is desirable, although probably not attainable at this late date, but an effort will be made in these reports to indicate which concept of the general practitioner is being discussed. The concepts described above may be indicated as follows: general practitioner (uncertified internist), general practitioner (multiple field), partial specialist, and personal physician—it should again be noted that a "personal physician" may be a specialist, an internist or even a full-time practitioner of one of the surgical specialties, he may think of, and treat, the patient as a whole individual and still refer the patient to someone else for the diagnosis and treatment of illnesses that fall outside his own specialty.

All four of the nonindustrial groups included in the present report have apparently decided that their organizations have no place for general practitioners of any description, all the physicians in these groups claim to be specialists and state that they limit their practice to their specialties. The industrial group contains 14 general practitioners, who seem in general to fall into the category of "uncertified internist." Of the 103 physicians in all five groups about whom information is available, therefore, 86 per cent limit their practice to one field of medicine (Table 3).

Of the 89 physicians who claim to be specialists, 57.3 per cent are certified by American specialty boards. Fifteen of the nonaccredited specialists are members of specialist societies, so that 74.2 per cent of the specialists are either certified or are members of specialist societies. There is no appreciable difference in this respect between the service and the reference groups.

The specialists in the hospital groups have the highest percentage of certification—66.7 per cent. The figure for the private partnership groups is 57.5 per cent, and that for the industrial group 42.1 per cent.

The specialists forty years of age and over have a higher percentage of certification than those under forty, but it may be noted that all the uncertified specialists under forty about whom information is available have applied for certification, whereas only 17 per cent of the uncertified specialists over forty have applied.

The three hospitals of which the groups form the complete staffs have authority to train physicians for one or more specialty boards.

Professional Supervision

It seems obvious that if a medical group is to continue functioning as an organized entity, some degree of professional supervision must be necessary, but only three of the groups reported that there was any direct supervision, even of the younger members. The director of one of the other groups believed that sufficient supervision of the members was attained at staff meetings during discussion of case reports,

whereas the fifth reported that there was no official attempt at supervision. In the opinion survey, 74 per cent of 84 physicians considered professional supervision, direct or indirect, to be desirable, whereas only 46 per cent of these physicians believed that there was any supervision of their own practice.

No special correlation between age and attitude is evident in this question of professional supervision, nor is there any marked distinction between service and reference groups.

Medical Staff Meetings

Staff meetings of the whole group are held regularly in each of the five groups. The frequency of these meetings varies from once a week to once a month. Case reports are common to all such meet-

would co-ordinate and interpret to the patient the findings of other specialists to whom he might be referred. The same four groups in which the patient is the responsibility of a single physician in a given illness report that their patients, as a matter of policy and as a general rule, have personal physicians within the group membership. This relation is permitted in the fifth group if the patient expressly desires it. In all groups, the personal physician is ordinarily selected by the patients concerned.

This question was also covered in the opinion survey, the physicians being asked whether they considered it medically desirable for each patient to have a personal physician. Of 83 physicians, 76 per cent replied in the affirmative and 22 per cent in the

‡This general practitioner has applied for certification in internal medicine.

ings, death reports are considered by four of the groups, and special reports by staff members and a journal club are parts of the programs in two.

Responsibility for Patients

In all but one of the groups — a hospital service group — the patient is primarily the responsibility of a single physician during a given episode of illness. In that group there is, in general, departmental rather than individual responsibility.

In the groups in which the patient is primarily the responsibility of a single physician, selection is usually made by the patient, although a referring physician outside the group may, in two groups, request the services of a particular physician. In three groups, a patient who has no preference is usually assigned to an individual physician by a nonmedical admitting officer.

There has been considerable discussion of the place of the "personal physician" in group practice — that is, one who would develop an intimate physician-patient relation with the patient and who

negative, 2 per cent were noncommittal. Three of the groups were almost unanimous in favor of the personal physician relation in group practice, about two thirds of the fourth (a hospital service group) replied affirmatively, and the fifth group (a hospital reference group) had a majority (9 of 16 members) who considered it medically inadvisable or unnecessary for each patient to have a personal physician. Interestingly enough, this was not the group that has departmental rather than individual responsibility for the patients.

Among 48 physicians in four groups who thought that each patient should have a personal physician, 29 would permit the patient to choose any member of the group. Fourteen physicians believed that the personal physician should be chosen from among the general practitioners, and 5 that he should be chosen from among the internists of the group, although one of these wished to exclude physicians in the medical subspecialties.

There was no particular difference in attitude between service and reference groups concerning re-

sponsibility for the patient. The age of the physicians questioned also had no bearing on this point.

Medical Records

It is implicit in the hospital-standardization program of the American College of Surgeons that a good system of medical records (both well designed and well kept up) is essential to the operation of a first-class hospital. Outpatient records cannot be expected to attain the same standards of completeness required of hospital records, but in view of the fact that patients of a medical group are often seen by more than one physician, it seems reasonable to expect that groups should keep more complete medical records than most individual practitioners do. Clark and Clark⁶ state that the essence of group work is the co-ordination of the various departments and that experience has demonstrated that the quality of the medical records in a group-practice organization reflects with remarkable accuracy the degree of co-ordination it has achieved. This statement has been taken as a working hypothesis in both the interview study and the record study, subject to confirmation or revision by the accumulation of data.

As part of the interview survey, the medical-record librarian is interviewed, and detailed information is obtained about all aspects of the record system. An attempt is also made to evaluate the extent to which the system is followed in actual operation.

It should be noted that all the groups studied were (or recently had been) shorthanded because of the war, both in physicians and in clerical help, and that all of them commented that their records at the time of the study were less well kept than before the war, all were hoping to improve the keeping of medical records when the manpower shortage became less acute.

Probably the most important single question about the systems of medical records used by groups is whether the records are kept in a unified form, with all physicians who see a patient having access to and making entries in the same record. A second question of significance is the relation of the hospital records of hospitalized patients to the outpatient records. The data presented below relate only to these two points and do not include consideration of such details of record keeping as diagnostic nomenclature, arrangement of records, filing systems and completeness with which the records are kept. Some of these factors are considered more fully in a future record study, which will be reported separately.

All four nonindustrial groups have unified systems of medical records. In the three groups that are integrally affiliated with hospitals, there is a true unit system, the clinic and hospital records of each patient being filed together in a single folder under one unit number. The fourth group has a unified record system for patients seen in the office or at home, with all such visits of a given patient recorded on the same form. In the industrial group, each family is assigned

a number on the first visit of the worker or one of his dependents, but each department, in each of the two clinics that this group operates, may keep its own file of records, so that the record of a given patient may be kept and filed in several scattered fragments.

It has already been noted that three groups maintain an integral hospital-clinic unit record system of hospital records. The other groups usually enter a short note on the clinical record that the patient has been hospitalized, but as a rule few details of the patient's treatment or course are included.

Qualifications for New Members

Information on the question of qualification was obtained from two groups. In one, a hospital service group, all new members must be certified specialists. In the other group, also a service group, a general practitioner is required to have had more than one year of hospital training, and a specialist must have the full qualifications for an American specialty board, but need not actually possess a board certificate.

Postgraduate Study

Although only one group specifically required younger men to take formal postgraduate study in 1944 and 1945, all encouraged such studies. A member of one of the groups was given leave of absence with pay for a full year to continue studies in orthopedic surgery, and another physician had spent several weeks in postgraduate study. A number of physicians had taken, or were taking at the time of the study, shorter postgraduate courses. Visits to outside medical centers, often referred to as "clinic trips," were more frequent than formal postgraduate work, but were not a definite requirement in any group.

FINANCIAL ARRANGEMENTS

Source of Income

All but one of the group depend principally on fees-for-service for their income. The exception is the industrial group, which is entirely supported by the sponsoring corporation. In all the fee-for-service groups, charges are said to be comparable with those made by local individual practitioners. Charges are adjusted to the patient's ability to pay, although in only one group is this ability formally investigated. In three groups the ability of the patient to pay a specified fee is determined initially by the business-office personnel, whereas the patient's physician makes this determination in the fourth group. Any question concerning a medical bill is resolved by the business manager in one group, and by the physician involved (if necessary, in conjunction with the medical director) in the other three. In one hospital group the fee schedule is publicly listed.

Distribution of Income

From the point of view of the physicians who practice in groups, the problem of income distribution is of fundamental importance, since on its satisfactory solution depend to a considerable extent the morale of the members, the avoidance of internal friction and even the continued existence of the group. Furthermore, the method of income distribution may influence the type of medical care given—the most obvious example is the effect on intragroup consultations. Some of these methods place a premium on the extensive use of consultations, whereas others tend to penalize the use of consultations and place a premium on one member's keeping and treating a patient as long as possible. The ideal income arrangement should be such as to encourage the liberal use of consultations when indicated but not to place a premium on unnecessary consultations.

Examples of three methods of income distribution are furnished by these five groups, although it should be noted that none of them use what is probably the commonest method—that is, payment to each member of a specified percentage of the total net income of the group, which may be determined annually or may depend on point scores attained by members during the year.

The two private groups differ in their arrangements for sharing the net group income. In one, the income is divided among the members according to the money value of the work done by each department. In the other, each member of the group, whether partner or employed associate, is paid a salary, which varies according to a number of factors. The surplus net income is then divided into equal shares among the partners, each senior partner receiving a full share and each junior partner a half share. In both hospital groups and in the industrial group, all the physicians are paid salaries that are fixed annually. Training, experience, competence and length of time with the group all contribute to the salary determination in the four groups in which the salary is paid. In one of these groups, account is also taken of the money value of the work done by the various departments during the preceding year.

In the opinion survey, all 13 members of one private group expressed a preference for a salary in addition to share, whereas 14 of the 16 members of the other private group preferred a straight percentage distribution. Two members of this group regarded a fixed salary as preferable. There was lack of agreement on this question among the three groups whose members are paid on a fixed-salary basis: in one, all the members considered a fixed salary to be the preferable type of income distribution, whereas a majority of the other two groups (12 of 19 members, and 7 of 12 members) believed that payment should be on the basis of salary in addition to share.

Fiscal Analysis

Since figures were obtained as confidential information, it is not possible to publish any analysis of the actual magnitude of income and expenditures. A few words may be said, however, regarding the proportion of gross income distributed to physicians, which was ascertained for three of these groups. In the hospital groups, the percentage relation between the amount paid to the physicians and the amount received by the hospital for professional services was considered to be the percentage of gross income distributed to the physicians. In the three groups from which this information was obtained, the percentages distributed to the physicians were 61.2, 67.3 and 72.1. It may be noted that Rorem,⁴ in studying twelve clinics in 1930, found distribution percentages ranging from 54.6 to 72.2, and that a poll in 1944, covering over 5000 physicians throughout the country, showed an average ratio of net income to gross income of 63.9 per cent.⁶

VOLUME OF WORK IN 1945

Volume figures are difficult to get and even more difficult to interpret, since groups vary widely both in the type of figures that they keep and in the completeness with which they keep them. It has been found, in other groups as well as in the five reported herein, that the annual number of new patients seen and the total annual number of clinic visits are almost always obtainable. The number of actual patients seen in a year is almost never obtainable, and in many cases the total number of clinic visits is not differentiated to show the number of visits to physicians and the number of visits (for x-ray examination, laboratory study, physiotherapy and injection by nurses) on which the patients were not seen by physicians. Records of home calls are likely to be incompletely kept, and in the groups without integral hospital affiliation, the statistics concerning hospitalized patients are often incomplete.

In an attempt to estimate patient load per physician, a further complication is caused by the fact that the present figures relate to 1945, when all the groups had men in or returning from the armed forces. An estimate of the number of physicians practicing with each of the five groups in 1945 was therefore made, the portion of the year during which returning or new members practiced with the group and the estimated fraction of time contributed to the group by part-time members being taken into account (Table 4). These figures, although somewhat arbitrary, are thought to give a reasonably accurate picture of the actual man-years worked in each group in 1945.

A special problem regarding the hospital groups, especially those that do a large volume of referred work, concerns the definition of "new patient." The study was designed to include only outpatients, and in groups not integrally affiliated with hospitals, the

figures obtained ordinarily referred only to outpatients, but the groups associated with hospitals vary in their practices concerning new patients who are hospitalized on their first visits. In one group, practically every patient who is hospitalized is first examined as an outpatient, and this is counted as an outpatient visit. In other groups, patients referred from outside physicians are admitted directly to the hospital and are not counted as having had an outpatient visit. Some of the variations in Table 4 may be related to this factor.

Number of Office Visits and Home Calls

Office visits by patients to physicians and the total number of clinic visits are presented in Table 4.

were 6355 home calls in 1945, when the group contained 9 physicians. The specialty reporting most home calls was pediatrics, which averaged 3230 calls per physician. Internal medicine was next, with an average of 1224 calls per physician.

Number of New Patients

It is hoped that this figure, interesting in itself as a crude index of volume, and hence of the degree of acceptability of group practice to the public, will also serve as a criterion of the amount of reference work done in a group. One would expect that a purely service group taking care of a continuing clientele, would have a relatively small number of new patients per physician, or per 100 office visits,

*According to a study conducted by Cioceo and Altman⁷ in 1942, the average annual patient load of 265 specialists in Baltimore, 198 in the District of Columbia and 175 in Georgia was respectively 3400, 3485 and 4700.

†Includes office visits to physicians and other visits for x-ray and laboratory study and so forth during which patients are not seen by a physician.

‡Figures from two groups.

§Figures from three groups.

In the three groups in which visits to physicians were distinguished from total clinic visits, the number of visits per physician ranged from 1321 to 5884. Total clinic visits, determined for all five groups, ranged from 1321 to 8159 per physician. Both the office figures in this column (1321 and 1746) were reported by groups integrally affiliated with hospitals and do not reflect the amount of work done for hospitalized patients. In one of these, x-ray and laboratory work is done by the associated hospital, so that the total number of clinic visits is the same as the number of office visits to physicians.

Comparison may be made between the number of office visits per physician in the two groups made up entirely of specialists and the figures obtained by Cioceo and Altman⁷ in a study of 636 specialists in Baltimore, the District of Columbia and Georgia. One group reports a much smaller patient load than the Baltimore specialists, whereas the patient load of the other is exceeded only by that of the Georgia specialists.

The industrial group and one of the private service groups were the only ones reporting any appreciable number of home calls. In the latter group, there

and that a purely reference group would have a large percentage of new patients.

This relation does not obtain in the four groups from which new patient figures were obtainable, but it may be pointed out again that three of these groups are integrally affiliated with hospitals, and there is reason to believe that in two, many patients are admitted directly to the hospital and are not included in the tabulation of new patients, although their hospital care actually devolves on the group members. Since hospital admission figures do not ordinarily distinguish between old and new patients, the extent of this under-reporting cannot be determined, but the direct hospital admissions almost certainly confuse the true picture.

Volume of Surgery

Comparable figures on volume of surgery were obtained from the three groups associated with hospitals. The totals for all operative procedures in 1945 (except oral surgery) were 4921, 4022 and 1409, respectively, or 547, 619 and 403 operative procedures per active surgeon. In the first and third of these groups, eye, ear, nose and throat operations

were reported separately. If these operations and the corresponding surgeons are omitted, the figures for operative procedures in the two groups become 3615 and 1239, or 603 and 620 per active surgeon.

Volume of Obstetrics

Total deliveries in four groups, including stillbirths, were 1520, or 253 per obstetrician. The volume of obstetrics does not seem to be correlated with the service or reference classification, but the

OPINION

In an effort to determine what the physicians in group practice think of the major controversial points connected with this technic for furnishing medical care, an opinion survey of individual members was carried out. In the first three groups, this was done entirely by interviews, the analyst filling out the schedule form after completion of the interview. Beginning with the fourth group, each mem-

*The wording of this question in the present interview outlines is as follows: "The following are the chief advantages that have been claimed for group practice. On the basis of your own experience, please check the three (no more) most important reasons why you think that group practice is preferable to individual practice (if an advantage that you consider to be one of the three most important is not listed, write it in)." In the first three groups, no list was presented; each physician was asked to name the advantages and if more than three were named, the first three mentioned were used in the tabulation presented above.

†Included 48 physicians.

‡Included 36 physicians.

§Included 84 physicians.

hospital groups were substantially higher in the number of deliveries per obstetrician than the private partnerships. The ratio for the two hospital groups was 280 deliveries per obstetrician, whereas that for the private partnership groups was 227.

Deaths

Information regarding deaths of hospitalized patients was obtained from four groups, three of which make up the entire hospital staff. The maximum death rate was 48 per cent of hospital admissions, and the mean was 31 per cent. Information on autopsies was obtained from the groups. The autopsy rate ranged from per cent in these four groups, with an 76 per cent *.

Medical Association requires a minimum autopsy rate
hospitals approved for internship and residency

ber has been asked to fill out the form himself, although it has proved most satisfactory to have the analyst present when he does so, to answer any questions of interpretation that may arise. Schedule revisions have also involved considerable rewording of some questions in the interest of clarity and precision. For this reason, the results are not comparable in all respects for all five groups.

The controversial questions considered in the present report are the advantages and disadvantages of group practice, the minimum number of physicians necessary for efficient group practice, and specialties. The results of the opinion survey about other questions are reported above, in the discussions of professional standards and income distribution.

Advantages and Disadvantages

A compilation of the principal advantages and disadvantages that have been claimed for group practice was presented in the previous paper.¹ During the course of study, changes in the method of approaching this question have seemed necessary. In the first three groups, each member was asked to name the principal advantages and disadvantages, but this technic caused serious difficulty in the analysis of the answers, even when the analysis was limited to the first three answers of each member

must therefore be interpreted cautiously. On several of the items the last two groups differed sharply from the first three, and from the data it cannot be determined whether these differences have real meaning or are related to the change in study technic.

The last two groups rated "freedom to do one's best work and to obtain laboratory work and consultations without restrictions" as the most important advantage of group practice. After this was "groups give their patients better medical care, by providing facilities for easy consultation, formal and

General hospitals approved by American College of Surgeons (with regular staff meetings) many specialists and better laboratory and x-ray facilities) more effective than medical groups in stimulating physicians' professional advancement and in providing highest type of medical care for patients‡	10	27.0	1	2.7	11	29.7	16	43.2	10	27.0

*Both these groups are service groups and the answers recorded apply only to service groups.

†The present schedules consider the following additional item: "Group practice yields smaller financial returns to the well trained specialist, considering his career as a whole. The two groups reported were not asked to rate this statement."

‡There is some doubt whether all respondents made the desired distinction between groups whether or not they are associated with hospitals and general hospitals not staffed by groups. The wording in the present schedule is: "General hospitals not staffed by groups but approved by the American College of Surgeons, are more effective than medical groups in stimulating the physician's professional advancement and in providing the highest type of medical care for the patient."

beginning with the fourth group, a list of advantages was drawn up, and each member was asked to check the three that he considered most important. A similar list of disadvantages and criticisms was drawn up, but each physician was asked to rate the degree of truth or falsity of each one, on a scale of five (strong and weak positive, neutral or no opinion, weak and strong negative).

The list of advantages presented for rating, in the order in which they are arranged in the schedules, is shown in Table 5. The answers received from the members of the first three groups were fitted as accurately as possible into the present list, the first three advantages mentioned by each physician being used. It is obvious that the first three advantages mentioned by a respondent are not necessarily those that he considers most important, and the results

informal, and for laboratory work," whereas in third place was "professional development stimulated by close professional contact with other members."

The first three groups gave first place to "groups give their patients better medical care and so forth," second place to "satisfaction of working in an atmosphere of professional co-operation" and third place to "freedom to do one's best work and so forth."

Because of the complete change in the technic for recording disadvantages, comparable figures were not obtained from all five groups. The disadvantages most frequently mentioned in the first three groups were as follows: a well trained specialist makes less money in group practice than in individual practice (mentioned by 29 of 48 physicians), and there is likely to be animosity toward the group

cytic cells were predominantly mature. Relatively few cells of myelocytic stages were noted. There was a marked increase in the percentage of eosinophils. Polymorphonuclear and metamyelocytic stages were present. There was a slight increase in plasma and reticulum cells. Megakaryocytes were present in a fair number, actively producing platelets. The diagnosis was splenic-vein thrombosis.

X-ray examination disclosed no esophageal varices.

Dr Louis Weissfuse made the following diagnosis and comment:

The diagnosis is splenic-vein thrombosis, with infarction of the spleen. The diagnosis of splenic-vein thrombosis was suggested by Dr Dameshek on the basis of personal observations. In these cases there was a history of hematemesis since early childhood, splenomegaly after the episode of hemorrhage without the occurrence of cirrhosis of the liver. At autopsy these cases were found to have been due to thrombosis of the splenic vein, with return flow of blood through the vasa brevia of the stomach and with dilatation and subsequent rupture giving rise to the episodes of hematemesis. None of the cases showed any evidence of cirrhosis of the liver. In the patient under discussion all tests revealed the liver function to be perfectly normal. There was no evidence of esophageal varices. The therapy in these cases has thus far been unsuccessful. Splenectomy has been ineffectual in relieving the hematemesis and has frequently given rise to postoperative thrombocytosis and thrombosis of veins throughout the body, with subsequent death.

Dr Leonard suggested that splenectomy be performed with the use of Dicoumarol to prevent postoperative thrombotic episodes. After consultation with Dr Dameshek it was decided to perform splenectomy.

The patient was admitted to the Jordan Hospital on January 10, 1947, and operation was performed on January 11. He was given pontocaine-glucose by fractional spinal method supplemented by Pentothal Sodium and nitrous oxide and oxygen. The abdomen was opened through a long left upper paramedian incision. Because of the patient's narrow build this incision was crossed just above the umbilicus by a transverse incision transecting the left rectus muscle and splitting the internal oblique and transversalis muscles. Excellent exposure was obtained.

The lower half of the spleen was found to be replaced by a large unilocular, smooth, symmetrical cyst. Numerous adhesions to the left anterior and lateral walls and to the splenic flexure of the colon were freed manually. The spleen and cyst were easily delivered. The presplenic fold was cut, and the lower portion of the gastrosplenic ligament was clamped, cut and ligated. With the specimen held medially the tail of the pancreas was freed from the hilus, and the splenic vessels were secured individually after opening of the lienorenal ligament. The remainder of the gastrosplenic ligament was clamped and cut, and the specimen removed. All vessels were individually ligated with No. 1 chromic catgut. Through the lesser peritoneal cavity the splenic vein was exposed at the upper border of the pancreas, and no evidence of preoperative thrombosis was noted. The liver was normal to inspection, and no biopsy was taken. The wound was closed in layers with interrupted cotton sutures.

The patient received a transfusion of 500 cc of citrated blood during the operation, and he left the operating room in

excellent condition. The pathological report by Dr Frank Mayner was as follows:

The specimen consists of a spleen measuring 19 by 10 by 8 cm (Fig 2 and 3). One pole comprises a large cyst measuring 10 by 10 by 8 cm. The outer surface is smooth. It is filled with semisanguineous fluid. The inner surface is rough, owing to the deposition of coagulated blood. The wall measures less than 0.1 cm in thickness. The cyst wall is intact throughout the specimen and in the portion next to the spleen proper. No communication is found with any part of the spleen. The area nearest the spleen contains coagulated blood. Section of the spleen shows nothing unusual. The organ is firm in consistence and reddish purple, and the malpighian corpuscles are not seen.

Microscopical examination of the cyst reveals a few red cells near and attached to the fibrous tissue lining the thin wall. The wall consists of fibrous tissue measuring in thickness between 15 and 20 cells. Section of the spleen shows prominent sinuses and pulp, which are empty and contain little or no blood. The capsule and trabeculae are normal. The malpighian corpuscles are moderately hyperplastic. The diagnosis is hemorrhagic cyst of the spleen.

The patient had an uneventful convalescence and was discharged from the hospital on the 10th postoperative day. Since discharge he has felt better than he had in years and is gaining weight steadily. He has no more pain and so far has had no complaints. When he was seen on February 28 by Dr Dameshek, physical examination and blood studies were completely negative.

SUMMARY

A case of false cyst of the spleen of the hemorrhagic type is reported. Because of hematemesis a preoperative diagnosis of splenic-vein thrombosis was made. The etiology of the hematemesis could not be explained after thorough study.

FAILURE OF THE PERITONEAL-BUTTON OPERATION FOR ASCITES

Report of Two Cases

KENNETH J. WELCH, M.D.*

BOSTON

THE surgical treatment of patients with recurrent massive ascites that requires frequent abdominal paracentesis has long been a challenging problem. Operative procedures designed to remedy the defect have carried an appreciable mortality, particularly in patients with portal obstruction due to hepatic cirrhosis who develop ascites relatively late in the course of the disease. Such procedures fall into several well defined groups. Some of these are designed merely to rid the patient of an oppressive volume of fluid, others attempt to eliminate factors in the production of ascitic fluid, and still others attempt to improve the body economy by returning water, electrolytes and protein to the general circulation. To this last group belongs the peritoneal-button operation, in which a flanged glass tube is inserted between the peritoneal cavity and a pocket made in the subcutaneous tissues of the anterior abdominal wall. This has the theoretical advantage of providing a constant slow egress of the patient's own blood transudate and the practical advantage of being a relatively simple operation that can be done under local anesthesia. Details of this procedure have been described by Crosby and Cooney.¹ This principle has been employed with minor changes in technique and with varying degrees of enthusiasm over a period of years. Tannahill² reported the use of such a button in 1930. More recently, with the improved medical management of patients suffering from hepatic insufficiency and with better control of surgical infection, interest in this operation has been revived.

It is the purpose of this paper to report experience with 2 patients who were provided with peritoneal buttons and subsequently subjected to post-mortem examination.

CASE REPORTS

CASE 1 D V (PBBH A-47-32) a 57-year-old Greek kitchen helper with a known diagnosis of portal cirrhosis was admitted to the hospital for operation after a 3½-month period of recurrent ascites. During the month prior to admission this fluid reaccumulated after paracentesis at 10-day intervals to the point of producing respiratory distress. On November 22, 1946, a glass peritoneal button of the Cooney type was inserted. The postoperative course was uneventful and the patient encouragingly developed marked edema of the lower abdominal wall and genitalia. He was discharged from the hospital 15 days later with no evidence of reaccumulation of peritoneal fluid. On December 18, however, less than 1 month after operation fluid had reaccumulated to that he again required paracentesis. During the next 3 months, until the time of death, a total of 46,700 cc. of ascitic fluid was removed from the abdomen at intervals ranging from 1 to 3 weeks. This fluid had a constant specific

gravity of 1.010 with total protein determinations ranging from 0.52 to 0.68 gm. per 100 cc. The serum protein was maintained in the range of 5.9 to 6.6 gm. per 100 cc., with albumin globulin ratios of between 0.5 and 1.0. The patient died on March 23, 1947, after a massive gastrointestinal hemorrhage from the rupture of an esophageal varix.

Autopsy. Post mortem examination revealed marked wasting of the upper part of the body, with a prominent abdomen and bulging flanks. Moderate edema of the genitalia was present, but no appreciable edema of the lower abdominal wall or of the lower extremities was noted. There was a 8-cm. inverted curvilinear well healed right rectus skin incision at the level of the umbilicus as well as numerous old and recent midline lower abdominal scars from the paracenteses. The umbilicus was flat, and no caput was seen. On opening of the peritoneal cavity 6500 cc. of cloudy straw-colored fluid was released. The peritoneal surfaces were white smooth shiny and opaque. The deep aspect of the peritoneal button was seen anorebed firmly in place, with a silk pursestring suture 5 cm. below and to the right of the umbilicus. The button was free of adhesions, the lumen was patent, and there was no increased peritoneal reaction in its vicinity. A segment of abdominal wall measuring 15 by 12 by 3 cm. was then removed from the right lower quadrant. The subcutaneous tissues appeared identical at the transected superior and inferior margins of the block and measured 1.5 cm. in thickness. A collapsed subcutaneous cystic space measuring 10 by 7 by 4 cm. and communicating with the peritoneal cavity was identified (Fig. 1). This had a smooth white glistening trabeculated surface with numerous shallow diverticulae at its margins. There was a single firm band of scar tissue running from the floor to the roof of the cavity in the vicinity of the button. This band whose appearance was entirely similar to the previously described peritoneal surface, could be seen arching evenly into the defect provided by the button. The glass button was freely movable within its tract and there was no visible reaction about its flanged neck. The wall of this cavity could be identified as a tough fibrous layer 0.15 cm. in thickness. Beyond it the layers of the abdominal wall were readily defined. A zone of yellow lobular fatty tissue separated the cyst wall on one side from the anterior rectus sheath and on the other from Scarpa's fascia. Microscopic sections taken from the superficial and deep layers of this wall (Fig. 2) presented evidence of an old inflammatory process with formation of a layer of dense poorly vascularized fibrous tissue. There was some scarring of the adjacent fat, with thickening of connective-tissue trabeculae and occasional perivascular foci of mononuclear inflammatory cells. There was a separate thin cellular lining layer composed of flattened elongated, darkly staining cells. Additional findings consisted of a diffusely nodular firm liver weighing 950 gm. histologic examination of which revealed toxic cirrhosis, an engorged spleen weighing 340 gm. and a blood filled upper gastrointestinal tract with a well defined perforation of the esophageal varix.

CASE 2 D B (PBBH A-46-148) a 46-year-old federal employee gave a history of having consumed over a pint of whiskey a day for many years. He was admitted to the hospital in August, 1946 with a diagnosis of portal cirrhosis following 4 months of recurrent ascites that required frequent abdominal paracentesis. On August 16, a Cooney type of peritoneal button was inserted. In spite of this procedure fluid continued to accumulate and repeated paracenteses were again necessary. One month after operation 9000 cc. of fluid was removed and 8 days later at the time of death a massive collection of ascitic fluid had again developed. The fluid obtained had a low specific gravity with a total protein of 0.27 gm. per 100 cc. The total serum protein in

*Graduate assistant in pathology, Peter Bent Brigham Hospital.

that period varied from 5.3 to 5.7 gm per 100 cc, with albumin-globulin ratios of from 0.3 to 0.5. The hospital course was unremittingly downhill, with signs of generalized

the costal margin, and the umbilicus was everted. There was a 9-cm, healed, curvilinear incision, with the convexity downward, located 3 cm below and to the left of the umbilicus.

FIGURE 1 Portion of Subcutaneous Space in Case 1

costal margins. The skin and scleras showed a yellowish discoloration, and there were numerous areas of ecchymosis. The superficial veins were prominent over the lower abdomen, upper chest and arms. The abdomen protruded 9 cm above

trabeculation at its margins. The cavity measured 4 by 2.5 by 3 cm. The flanged neck of the superficial portion of the button could be seen occupying the central portion of the floor of the space. When the peritoneal cavity was opened,

8600 cc. of thin straw-colored fluid was released. The subcutaneous tissues varied from 0.3 to 1.0 cm. in thickness. The peritoneal surfaces were smooth white and glistening but again opaque. The deep portion of the peritoneal button was readily identified. There was no increased peritoneal reaction in its vicinity; no adhesions were found, and the lumen of the button was patent. The peritoneal layer blended evenly with the wall of the canal provided by the button and was continuous with the lining of the subcutaneous space. Additional findings consisted of a firm diffusely nodular liver weighing 1160 gm, a noticeably distended portal vein, a large firm spleen weighing 495 gm, and evidence of the establishment of an elaborate collateral circulation. Microscopic examination of the liver and pancreas revealed extensive deposits of hemosiderin. This finding led to a primary diagnosis of pigment cirrhosis.

DISCUSSION

Although experience with the peritoneal-button operation for ascites is limited, the opportunity to study the reasons for failure in 2 consecutive cases presented itself. In both cases, subcutaneous pockets, which had dense, hyalinized, connective-tissue walls, communicated with the peritoneal cavity. The similarity of the findings in these cases suggests that the formation of such a pocket follows a predictable histologic sequence.

Several factors seem to be of importance in producing this situation. The limitation of the size of the cavity in each case to approximately the limits of the surgical dissection implies that there is a factor of operative trauma with a subsequent attempt at repair. The subcutaneous pocket is maintained by a constant outpouring of fluid from the abdominal cavity. The ascitic fluid alone at times may attain a hydrostatic pressure equivalent to 30 cm. of water. In addition, any sudden increase in intra-abdominal pressure is transmitted to this subcutaneous space. Thus, in Case 1 it was suggested that the patient had developed a ventral hernia at the site of operation because of a swelling that appeared in the erect position. This had the configuration of the cavity described and transmitted an impulse on coughing.

Infection in a subcutaneous dead space is often seen in other surgical situations and may increase the extent and degree of scarring. This is suggested in the microscopical section from the cyst wall in Case 1, in which residual foci of mononuclear inflammatory cells were found.

A high concentration of protein in ascitic fluid may, in some cases, be a factor in the formation of a fibrous barrier to absorption of fluid. Foord et al.³ in a study of ascitic fluid from patients with hepatic cirrhosis, found an average total protein of 1.32 gm. per 100 cc., with some as high as 3.09 gm. It cannot be said that the protein concentration was a major factor in the cases presented above, since at no time was the total protein content of ascitic fluid

recorded above 0.68 gm. per 100 cc. This value is well within the limits found in edema fluid obtained with Southey tubes from patients in congestive failure.⁴ Such a fluid would probably not initiate an active fibrosis.

At some time within the first month after operation the space thus maintained becomes lined with mesothelium but not until the lateral limits of the cavity have become permanently defined by marginal scarring. At this stage the situation approaches that of a bursal cavity, with a smooth gliding surface and an intervening fluid layer. When the abdomen is emptied by paracentesis this space becomes collapsed, but with reaccumulation of fluid it refills much like a "bay" of the peritoneal cavity. Any absorption that occurs from such a space is automatically limited by the small area of surface exposed. In addition, the added storage space provided in the 2 cases (250 and 25 cc. respectively) was insignificant.

SUMMARY

Two cases of hepatic cirrhosis requiring repeated abdominal paracentesis for recurring ascites and treated surgically with a peritoneal button are presented. The effects of these operations were considered negligible after periods of two to four weeks.

An opportunity was provided for post-mortem study of these cases with the discovery of a subcutaneous cystic space having a dense fibrous wall and communicating with the peritoneal cavity in each case.

It is suggested that the formation of a subcutaneous pocket with a dense connective tissue wall and a mesothelial lining follows a predictable histologic sequence. Because of the small area of surface exposed and the fibrous character of the wall, little absorption can take place from such a cavity.

The peritoneal-button operation did not provide an effective, sustained, slow egress of ascitic fluid in these cases.

Catheterization of the heart Forssmann,¹⁰ in 1929, introduced a long, radiopaque catheter first into his own antecubital vein and later into those of patients and succeeded in passing the catheter into the heart without injury. Until recently, this method has been used only occasionally, either for the study of blood pressure and oxygen content in the right side of the heart or for the direct introduction of contrast mediums into the heart. The procedure in the beginning appeared hazardous, and the results did not seem to warrant the chances that the investigator took.

The rapid progress of cardiovascular surgery in recent years, however, and the necessity for all available help in accurate preoperative diagnosis have stimulated further investigation with amazing results. Catheterization is usually performed in centers in which a cardiologist, a cardiovascular surgeon, a physiologist, a chemist and a radiologist work together to solve the puzzles of congenital heart lesions. Results have been published from several of these centers.¹¹⁻¹⁴

Sosman¹³ and Dexter¹⁴ have given an excellent description of the indications, technic, errors, results, interpretation and value of heart catheterization. A waxed, radiopaque catheter is introduced into the median basilic vein. The catheter has a slightly rigid bend near its end that allows guidance in the desired direction by twisting. Under fluoroscopic control the catheter is passed through the vena cava into the right auricle, into the right ventricle and finally into the pulmonary artery. For other investigative purposes it can be guided through the right auricle into the inferior vena cava. The pressure in these various parts of the heart and large vessels is determined through the catheter, and blood samples are obtained for oxygen-content determinations. Spot films of the catheter are taken in each position in which these determinations are being made. This results in an excellent charting of the conditions within the right side of the heart and the pulmonary artery. Abnormal variations in the pressure of heart chambers and pulmonary artery and of the oxygen content in various locations may be detected and they are often of diagnostic significance, as in interauricular septal defect, in interventricular septal defect, in pulmonary stenosis, and in patent ductus arteriosus. In addition, the abnormal communications within the heart may at times actually be demonstrated by the position of the catheter. The catheter may thus pass directly from the right to the left auricle, from the right into the left ventricle or, in cases of the tetralogy of Fallot, from the right ventricle directly into the overriding aorta. At the time of publication, the authors had performed catheterizations in 100 cases without mishap. Autopsies of patients who later died of causes not connected with the procedure failed to show evidence of damage to the endothelium of the superior vena cava, the right auricle, the

right ventricle, the pulmonary arteries or the valves. It is obvious that this procedure should be performed only when an adequate team is available. In the hands of such a team the information obtained is often invaluable.

Angiocardiography In a previous progress report¹⁵ the principle of angiocardiography was discussed. After several attempts by various investigators to demonstrate the heart chambers and the interior of the great vessels by injection of dye into the arm vein either directly or through a catheter Robb and Steinberg¹⁶ demonstrated a practical method in 1939. It consisted of radiography of the heart and great vessels following rapid injection of 30 cc of 70 per cent Diodrast (twice the concentration used in intravenous pyelography). Since the original publication, valuable information has been obtained by this method. The position, size and shape of the heart chambers, valves and great vessels have been studied, and knowledge obtained that had not previously been available. Many questions of topographic anatomy of the living person were clarified. It was possible to obtain a moving film demonstration of the flow of the dye through the vena cava, the right side of the heart, the pulmonary arteries through the lungs to the pulmonary veins, the left side of the heart and the aorta.¹⁷ This was an excellent demonstration of anatomy and physiology of the lesser circulation. The method was used successfully in the differential diagnosis of aortic aneurysms and mediastinal tumors. It was also applied for the study of congenital anomalies of the heart and great vessels. Intracardiac shunts were demonstrated, particularly those from the right side of the heart through a septal defect to the left side and aorta, as in the tetralogy of Fallot and Eisenmenger's syndrome.¹⁸ The patent ductus arteriosus itself was not filled with dye, but accompanying anomalies were visualized,¹⁹ as pointed out below. The method is not a part of the routine examination. It necessitates experience and a special team to produce satisfactory results and should be reserved for research centers.

Recently Chavez, Dorbecker and Celis²⁰ reported their results with injection of dye through a rather wide catheter, which was introduced in the jugular vein. This article is cited, not because this procedure is expected to be repeated by others (fatalities following the intracardiac injection of dye have been reported) but on account of the illustrations that were made possible by the introduction of dense dye into the heart chambers and the great vessels. They are of special interest in the study of congenital heart lesions.

Roentgenologic Studies in Specific Congenital Abnormalities

Patent ductus arteriosus In 1939 Gross¹ described the first successful closure of a patent ductus arteriosus. Four years later Donovan, Neuhauser and

Sosman²² reported from the same hospital the roentgenologic findings in 50 cases that had been verified at operation. This represented at that time a unique experience, since no one had previously had the chance to compare the roentgenologic appearance of the heart and great vessels before and after operation.

The previously vague and contradictory roentgenologic literature on patent ductus arteriosus was now on a solid footing.

The variations from normal found in order of frequency were dilatation of the pulmonary artery, which, although present in 82 per cent of cases, was rarely marked, cardiac enlargement, which was usually only slight and limited to the left side (large hearts were rare in uncomplicated patent ductus arteriosus), dilatation of the left auricle, engorgement of intrapulmonary vessels, which was usually not striking except when combined with endocarditis, exaggerated pulsation of the left ventricle and pulmonary artery, and increased hilar pulsation (so-called "hilar dance"), which was present in a third of the cases.

Postoperatively, the heart size was usually not much changed. Pulsations of the left ventricle and pulmonary artery were found to be decreased, the pulmonary vessels were often smaller than before operation, and the left auricle had decreased in size.

The roentgenologic examination alone does not establish the diagnosis, but it suggests the diagnosis, contributes important confirmatory evidence and bears important witness to the effectiveness of the treatment.²³

Angiocardiographic studies gave additional information. Steinberg, Grishman and Sussman¹⁹ found localized dilatation of the descending aorta in the region of the patent ductus arteriosus. It was present in 26 of 27 cases. In addition, the main pulmonary artery and its left branch were elevated as if drawn toward the isthmus of the aorta. Dilatation of the main and the major branches of the pulmonary artery was present in 75 per cent of cases. Various degrees of left ventricular dilatation were seen. The ductus itself could not be demonstrated by the opaque medium.

It is rarely necessary to apply angiocardiography to the diagnosis of patent ductus arteriosus. The main importance of studies like these lies in the additional information that is gained for routine roentgenologic examinations. Thus, it should be possible to demonstrate the localized bulge of the aorta during fluoroscopy.

At times, the scar of a closed ductus arteriosus can be seen in adults. A small area of calcification close to the upper edge of the pulmonary artery simulating a calcified lymph node was found to represent calcification in the scar.²⁴

Congenital heart disease with cyanosis. In 1945 Blalock and Taussig²⁵ reported the successful surgical intervention in cyanotic patients in whom the pulmonary circulation was impaired, usually owing to pulmonary stenosis and associated defects. The

condition is generally found in the tetralogy of Fallot (pulmonary stenosis, ventricular septal defect, an aorta that rides over the defect and right ventricular hypertrophy). The diagnosis is at times quite difficult, particularly if additional anomalies are present. The roentgenologist can be of help in some cases. The heart, even if not enlarged, shows an abnormal blunting of the elevated apex, the so-called "coeur en sabot" or "sheep's nose heart." The right ventricle is seen to be enlarged, and the pulmonary artery and its branches are small.

Roentgenologic examination is helpful in the differentiation of the tetralogy of Fallot from Eisenmenger's syndrome, a combination of anomalies similar to the tetralogy but without pulmonary stenosis. The clinical picture of the two conditions may be similar, but the Blalock operation is of no help in Eisenmenger's syndrome. Roentgenologically, the pulmonary artery is found to be normal or enlarged in contrast to its narrowing in the tetralogy of Fallot. Angiocardiography at times gives helpful information.¹⁸

Catheterization of the heart is valuable in the diagnosis of the tetralogy of Fallot. A low pressure in the pulmonary artery and an increased pressure in the right ventricle permit the diagnosis of pulmonary stenosis. At other times, the catheter can be introduced from the right ventricle directly into the overriding aorta and thereby can give a beautiful visual demonstration of the abnormal bloodstream. It is obvious that catheterization of the heart may be of help in the differential diagnosis of the tetralogy of Fallot and Eisenmenger's syndrome.

A great number of variations are possible between the tetralogy and Eisenmenger's syndrome, depending on the degree of collateral circulation for the lung. Bing²⁶ uses, in addition to catheterization, respiratory studies to determine the pulmonary blood flow. Eisenmenger's syndrome may be called one extreme of these variations with excellent blood flow into the lung through the pulmonary artery. Cases with complete absence or obliteration of the pulmonary artery (so-called "truncus arteriosus solitarius") represent the other extreme. In these cases the lung receives its blood supply from other sources, such as the bronchial arteries. Since the normal hilar shadows are produced by the branches of the pulmonary artery, it is not surprising to find an almost complete absence of the hilar shadow in these cases.²⁷

Vascular ring around trachea and esophagus. The normal aorta and the large vessels arising from its arch are the end result of a complicated system of six bilateral branchial arteries. This system represents an ideal opportunity for numerous congenital variations, and nature quite often has chosen abnormal variants, the majority of which, although they may represent interesting roentgenologic appearances, do not produce clinical symptoms. The right-sided aorta is the most characteristic example for such a variation. In this anomaly,

the aortic arch lies to the right and posteriorly to the esophagus instead of to the left and anteriorly, as in normal cases. Abnormal displacement of the esophagus and trachea characterizes this condition roentgenologically. Only in rare cases does it produce clinical symptoms such as dysphagia. The recognition of this anomaly is, however, important, since it is not infrequently associated with other congenital anomalies, as in the tetralogy of Fallot.

In certain cases both the right and the left sides of the aortic arch persist, and a vascular ring formed by the two arches surrounds the trachea and the esophagus. Roentgenologically, this anomaly was first diagnosed in 1925.²² Isolated cases have subsequently been reported. It was found that this arrangement at times produces definite clinical symptoms, particularly of the respiratory tract, including repeated episodes of upper respiratory infection starting in early infancy and stridor, which is more marked during feeding; dysphagia is less striking.²³

Recent successful ligation and division of one limb of the vascular ring with the resulting freeing of the trachea^{20, 21} have increased the interest in the roentgenologic appearance of this anomaly, particularly since the diagnosis mainly rests on the roentgenologic findings. Neuhauser²¹ describes 4 cases, 2 of which came to operation. The esophagus showed a round pulsating defect posteriorly at the level of the aortic arch. In the anteroposterior view at the same level the esophagus was slightly narrowed from both sides. The trachea just above the carina was seen to be narrowed and displaced anteriorly. The tracheal deformity is best seen after lipiodol installation but may be seen without lipiodol in anteroposterior, oblique or lateral views, if looked for fluoroscopically and with spot films.²¹ In some cases the descending aorta lies to the left of the spine, and in others to the right. A correct roentgenologic recognition of this course may be of importance prior to surgical intervention.²¹ A vascular ring may easily be missed on routine examination. It is the responsibility of the roentgenologist to think of this possibility, particularly in children with repeated upper respiratory infection and stridor. As stated above, the diagnosis usually depends on his examination. It is likely that some variations in the roentgenologic appearance will be noticed, with an increase in the number of cases observed and operated on.

Coarctation of aorta. The roentgenologic changes seen in coarctation of the aorta have been described in many papers. At times, the hypertrophy of the left ventricle, the widening of the ascending aorta, the small aortic knob, the peculiar notching in the upper portion of the descending aorta and, in particular, the erosion of the inferior edges of the ribs produced by the tortuous dilated intercostal arteries are so characteristic as to allow an unequivocal diagnosis. In other cases the roentgenologic findings are less marked. Recent successful resection of the coarcted area has permitted a check of the roent-

genologic findings.^{24, 25} Gladnikoff²⁴ analyzed the appearance of the left upper border of the cardiovascular shadows in operated cases. He emphasized the recognition of the dilated left subclavian artery, a medial displacement of the aortic arch and an indentation in the upper portion of the descending aorta as signs of coarctation. When these changes are present in the absence of the common, pathognomonic notched ribs they are of particular diagnostic significance.

Classification. The number of congenital anomalies of the cardiovascular system is so large that a simplified grouping has been found to be advantageous. The one generally used is that of congenital heart lesions with or without cyanosis. It is interesting to attempt a classification of these lesions from a completely different approach. Sussman and his co-workers²⁶ fully recognizing the present impossibility of establishing a complete diagnosis from x-ray study alone, attempt a roentgenologic classification of these lesions. They differentiate lesions with an enlarged pulmonary-artery segment of the cardiac contour, those with a normal or small pulmonary-artery segment and with right or left ventricular enlargement, right aortic arch, and dextrocardia.

Although progress in the diagnosis of these lesions has been so rapid that this classification appears incomplete and somewhat schematic in the light of newer developments, it is quite helpful and is particularly recommended as an introduction to the roentgenologic study of congenital lesions of the cardiovascular system.

A new monograph on the subject of congenital heart disease has been announced by Taussig, and will be available soon. It will represent the experiences of the Johns Hopkins' group, and should prove to be of great interest and value.

NEPHROGRAPHY

After the intravenous injection of organic iodine salts like Diodrast for the demonstration of the kidney pelvis and ureters, the shadow of the kidneys increases slightly in density. The increase in density is usually only minimal. Early observers, however, noted that if pyelography was performed while one ureter was acutely obstructed, a fairly marked increase in the density of the kidney might occur on the involved side. If the pain stopped spontaneously, a sudden outpouring of dye into the kidney pelvis and ureter took place, with a decrease in the density and size of the kidney. Wilcox²⁷ confirmed these clinical observations by experiments in rabbits. Clamping off of one ureter for forty-five minutes resulted in increased size and density of the kidney, but some dye was still excreted into the kidney pelvis. If the ureter was clamped off for sixty minutes, this excretion stopped while the kidney still increased in density. Immediately after release of the clamp the dye poured out into the kidney pelvis, and the kidney returned to its normal size and density. The accumulation of dye in the kidney

parenchyma during the ureteral obstruction was much greater than could be explained by accumulation of dye-containing blood in the kidney. Collection of dye in the uriniferous tubules following the increased pressure in the kidney pelvis was thought to be a decisive if not the entire reason for this phenomenon. More recent discussions on this subject are found in articles by Nowell³⁸ and by Florence, Howland and Weens³⁹.

This phenomenon is of clinical significance. If marked unilateral increase in the density of a kidney and no excretion of intravenous dye on the same side are observed, the presence of acute obstruction can be assumed, although the obstructing agent, such as a small stone or blood coagulum, may not be seen. The phenomenon also proves the presence of a functioning kidney in the absence of dye excretion into the kidney pelvis. In cases of long-standing ureteral obstruction with absent kidney function an increase in density will not take place during the intravenous pyelogram. Finally, the phenomenon proves for all practical purposes that the obstruction is acute.

For a number of years various authors have wondered whether it might not be possible to use this phenomenon for the diagnosis of localized disease in the kidney parenchyma. Recent papers in the literature have attacked this problem and shown some practical results. During intravenous pyelography in a patient with acute ureteral obstruction, Hellmer⁴⁰ saw increased density of the involved kidney with the exception of the lower pole, which kept its original density. A repeated intravenous pyelography a few days later, after the colic had subsided, showed excretion into the kidney pelvis. The pelvis was deformed by a tumor of the lower pole. In other words, during the phase of obstruction that apparently had been caused by a blood coagulum, the kidney had increased in density where normally functioning tissue was present but not in the region of the tumor. A similar appearance was produced in a patient who had a renal cyst and acute ureteral obstruction. In a third case of renal colic, an apparently normal kidney pelvis was seen on the involved side, but localized increase in density was noted in the kidney above the pelvis. Three and a half hours after the injection this density disappeared and a second smaller kidney pelvis was filled in the upper pole of the kidney. In other words, this patient had double kidney pelvises and ureters with transient obstruction in one of the ureters. Hellmer called the increased density of the kidney a nephrogram. A satisfactory nephrogram is observed only in the presence of acute ureteral obstruction.

Recently, Weens and Florence⁴¹ published their results with artificial nephrography. These authors introduced a Dourmashkin dilating bougie into the proximal or middle ureter. Then they gently dilated the small rubber bag at the tip of the catheter with 5 cc of mercury. This was followed by intra-

venous injection of 30 to 35 cc of Diodrast (35 per cent). If the injection was delayed by ten to twenty-five minutes after the dilatation of the bag only small amounts of dye were seen in the kidney pelvis, and a satisfactory increase in the density of the kidney shadow was obtained thirty minutes after injection of the dye. The kidney was also slightly enlarged. Normal density and size of the kidney reappeared a few minutes after deflation of the rubber bag. Some patients had no pain, others had mild or marked pain, but not enough to prohibit the procedure, if the patient was prepared with 20 mg of Pantopon. Transient hematuria (for not more than one day) was observed in 3 cases, but was probably not more than could be expected from instrumentation. The authors did not report cases in which their method had been of diagnostic value.

Further studies will be necessary to prove that this method is harmless. If so, it will add a new tool to our diagnostic armamentarium useful in individual cases, such as those of unexplained unilateral hematuria with normal routine intravenous and retrograde pyelograms.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., Editor

BENJAMIN CASTLEMAN, M.D., Associate Editor

EDITH E. PARRIS, Assistant Editor

CASE 33461

PRESENTATION OF CASE

A fifty-five-year-old housewife entered the hospital because of a mediastinal mass.

Eight years previously the patient had been admitted to the hospital for the first time because of a lump in the left breast. There were no other complaints. X-ray studies of the chest, spine and pelvis were negative. A radical mastectomy was performed. The pathological diagnosis was adenocarcinoma (Grade II). The axillary lymph nodes were not involved. A cervical polyp was also removed. This, when examined microscopically, showed extremely severe squamous-cell metaplasia. Sterilization doses of x-ray were administered to the pelvis, and the patient was discharged. Six months later she was readmitted for a hysterectomy. The resected uterus showed an inactive endometrium and chronic endocervicitis. She recovered uneventfully. For several years thereafter she felt perfectly well, and numerous examinations, including at least one chest x-ray film, were entirely negative. Approximately seven years after the original operation the patient reported for a periodic examination complaining of weakness, weight loss and nervousness of six weeks' duration. These symptoms had begun quite abruptly. In spite of a normal appetite she had lost 13 pounds during this period. There had been no intolerance to heat and moderate

palpitation and dyspnea on exertion. She had noticed no swelling in the neck or prominence of the eyes. The bowel habits remained unchanged.

Physical examination at that time revealed a well-nourished woman. The skin was warm and dry. There was a fine, even tremor of the hands and tongue. No abnormality of the eyes was noted. The chest and abdomen were normal. There were no enlarged lymph nodes. The thyroid gland was palpable but not enlarged and gave no bruit or thrill.

The blood pressure was 138 systolic, 80 diastolic, the pulse 100, and the respirations 25.

The basal metabolic rate was +15 per cent. Urinalysis was negative. The cholesterol level was 223 mg per 100 cc, and the cholesterol esters 141 mg. A blood Hinton test was negative.

A routine chest film showed an oval-shaped, soft-tissue mass of smooth outline, measuring 5 or 6 cm in its greatest diameter, in the region of the aortic arch. This mass compressed the trachea and displaced it anteriorly and slightly to the right and also displaced the esophagus somewhat to the right and posteriorly. Fluoroscopy confirmed the finding. The mass did not interfere with swallowing. The esophagus showed no motion in this region, and the mass appeared fixed to both trachea and esophagus. It did not pulsate but could not be separated from the aorta, which it seemed to displace slightly to the left. The heart and lungs were not remarkable. X-ray examination of the bones was negative.

A tracer dose of 100 millicurie units of radioactive iodine was given with 30.8 per cent excretion during the first twenty-four hours and 1.4 per cent during the second. The blood iodine was 8.7 microgm per 100 cc. Repetition of the basal metabolic rate and the blood iodine showed figures of +3 per cent and 5.3 microgm per 100 cc.

The patient was followed closely as an outpatient and improved a great deal during the next few months. The nervousness, palpitation and dyspnea gradually subsided without specific treatment. She gained several pounds in weight, and six months later was admitted to the hospital for study of the

mediastinal mass At that time she felt well, complaining only of slight palpitation on exertion She had never experienced any difficulty in swallowing or pain in the chest There had been a slight hacking cough for one or two years but no hemoptysis or increased sputum

Physical examination revealed no noteworthy abnormality The thyroid gland was not palpable, but there was slight tenderness to pressure over the right lower pole

The temperature was 98°F, the pulse 70 to 80, and the respirations 20 The blood pressure was 136 systolic, 90 diastolic

The x-ray appearance of the mediastinal mass was unchanged Review of the previous chest x-ray films showed that this same mediastinal shadow had been present five years before and had not changed during this period

An operation was performed

DIFFERENTIAL DIAGNOSIS

DR JOSEPH C AUB A sorely needed mastectomy had been done eight years before entry The uterine polyp probably never would have become malignant, and why so "much ado about nothing," I do not know At any rate, x-ray therapy was given, I suppose because of the breast carcinoma Why the uterus was removed puzzles me It makes me think that she was a nervous woman or had a nervous doctor, but I get the impression that she was nervous I do not know whether anyone has ever gone into the psyche of the patient at these exercises

Seven years later symptoms due to either a neurotic storm or hyperthyroidism developed That is suggestive of hyperthyroidism, although the basal metabolic rate was only +15 per cent The mass pushed the trachea forward not backward, and if this report is correct, it was fixed to the trachea, esophagus and aorta If it was a thyroid tumor it should not have been fixed to the trachea or esophagus and should not have been posterior to the trachea The description suggests a blood supply from the surrounding area, and therefore implies that the mass was not carried down into the mediastinum like a thoracic goiter

"A tracer dose of 100 millicurie units of radioactive iodine was given with 30.8 per cent excretion during the first twenty-four hours and 1.4 per cent during the second" That certainly is in favor of hyperthyroidism A hyperthyroid patient will hold on to a great deal of iodine and not excrete it The blood iodine was 8.7 microgm per 100 cc If that was protein-bound iodine, it was above normal values and also suggests hyperthyroidism Nothing is said about scanning the thyroid gland or mediastinum to see if too much radioactive iodine was retained there

If the thyroid gland in the neck were shielded — and the amount of radioactive iodine in the medias-

tinum so determined — and if found high one would have to make a diagnosis of mediastinal thyroid tissue No such therapy as thiouracil was given Is that right?

DR TRACY B MALLORY Yes

DR AUB The second basal metabolic rate was +3 per cent, and the second blood iodine was 5.3 microgm per 100 cc Those are within normal limits, so that we must decide that she did not have hyperthyroid disease The hacking cough is much more suggestive of neurosis than hyperthyroidism, although patients with mediastinal thyroid glands may cough The lack of pain in the chest and the lack of sputum and hemoptysis are against a recurrence of the breast tumor

May we see the x-ray films?

DR STANLEY M WYMAN The original film was initially interpreted as normal I certainly would call it normal if reading it routinely As the subsequent examinations unfold, however, and the mass in the mediastinum is noted, it is apparent in review of the first film that there is increased density and that the tracheal shadow does not come down to the upper border of the aorta as it should This mass is really ovoid It comes down very close to the aorta and pushes the trachea to the right In the lateral view the trachea is seen to be displaced anteriorly and is considerably compressed, measuring half the normal diameter The esophagus is pushed backward This is a plain film showing the mass The oblique view shows a good mucosal pattern in the esophagus, with no significant delay or obstruction The mass is in contact with the wall of the esophagus, and probably adherent to it The same can be said of the trachea in this view, because the outline of the trachea is slightly irregular and nodular

DR AUB Is the trachea definitely anterior to the mass?

DR WYMAN Yes, and the esophagus is posterior to it The statement is made that the mass could not be separated from the aorta, but I believe that one can outline the aortic arch at that point, with the mass lying to its right The mass apparently has not changed in five years

DR AUB The first decision to make is whether this mass was benign or malignant Did it have anything to do with the carcinoma of the breast, or was it related to the uterus? Was this an additional cancer? I do not believe that it was a malignant tumor It had been present for five years and had not enlarged It was adherent, which is suggestive of malignancy, but the edges were smooth It did not grow into the esophagus There is no evidence that it was growing into the trachea, except for cough, which may have come from impingement on the trachea Therefore, I think that this was a benign tumor I shall be disappointed if that diagnosis proves wrong

The next question is whether this was a benign tumor in contradistinction to intrathoracic thyroid tissue. That seems to me to be the significant differential diagnosis in this case. There are two important points. That the mass was adherent to the esophagus and trachea and did not invade either of them suggests to me that the blood supply was local rather than one carried down from the neck. Therefore, the trouble may have been an inflammatory condition, such as tuberculosis, rather than a benign tumor, but since I do not see any suggestion of tuberculosis in the lung, I have no right to make that diagnosis. The second important factor—and one that I think is also against a mediastinal thyroid gland—is the position of the mass behind the trachea. I do not know of a mediastinal thyroid gland in that position.

There is evidence for hyperthyroidism. As I have already said, the patient appears to have been a nervous woman. Certainly, she was willing to be operated on. There is not a great deal to suggest hyperthyroidism, except for the first radioactive iodine test, and I am not sufficiently convinced about that to lay too much stress on it. At any rate the differential diagnosis rests between hyperthyroidism with a substernal goiter and a benign tumor that had been present a long time. Let us discard the thyroid gland because of the position, adherence and lack of consistent evidence of toxicity. Let us say that it was a benign tumor. If a benign tumor, it must have been one of the connective-tissue tumors, and, on the whole, judging by the law of chances, it would be a neurofibroma. This last part is pure guesswork. I think that the patient should have been operated on if this was an adenoma of the thyroid gland and even if it was a benign tumor, because there was no way of determining what it was, such an operation is good cancer therapy, to avoid the possibility of malignancy and metastasis from the breast, which I do not consider likely. I should guess mediastinal adenoma of the thyroid, and I believe that that diagnosis is wrong. What was the hospital preoperative diagnosis?

DR HELEN B. PITTMAN: We went through all the same troubles that Dr. Aub has, but for a much longer time. The patient was not a nervous woman. She was co-operative and somewhat irritated that we paid so much attention to the symptoms that did not bother her. Hysterectomy was done because she had an easily bleeding cervix that looked abnormal, and we thought that that should be removed. We followed her in the thoracic clinic, and Dr. Schatzki did a great deal of fluoroscopy on her. The initial group that saw her thought that the diagnosis fell between metastatic node and mediastinal thyroid gland, and since one does not operate on metastatic lymph nodes in the mediastinum, she was given iodine, to determine if we could pin the trouble on the thyroid gland.

She remained in good health, and the mass did not change in appearance. It was decided that it was benign.

Some months later the opinion was that the lesion was probably either a bronchiogenic cyst or an intramural or extramural tumor of the esophagus, which ought to be removed as good general prophylaxis.

DR EARLE M. CHAPMAN: This patient was seen in the Tumor Clinic, where opinion varied. I can sum it all up by reading the final note made by Dr. Cope: "The diagnosis is impossible, short of operative exposure."

DR DONALD S. KING: Dr. Castleman thinks that I ought to be able to name this lesion, but I cannot. I did not see the patient. It seems to me more like a tumor in the esophageal wall. That is the best that I can make of it.

DR WYMAN: I would be surprised if this were a tumor in the esophageal wall, Dr. King.

DR KING: Could it not be in the wall and not involve the mucous membranes?

DR WYMAN: Such tumors usually cause more spreading of the esophagus, especially a mass of this size. With intramural lesions the esophagus appears more adherent, is displaced more and is thinned.

DR KING: Yes, but I remember a case that did not, I therefore think that it is still possible that this was an esophageal-wall tumor.

CLINICAL DIAGNOSIS

Mediastinal cyst

DR AUB'S DIAGNOSIS

Benign intrathoracic tumor of connective tissue
(not intrathoracic goiter)
Neurofibroma?

ANATOMICAL DIAGNOSIS

Bronchiogenic cyst

PATHOLOGICAL DISCUSSION

DR MALLORY: This patient was operated on by Dr. Richard H. Sweet. He found a tumor mass very densely adherent to the trachea, to the esophagus and to nearly all the other surrounding structures. In attempting to mobilize it he broke the wall and released some mucoid fluid similar to that commonly seen in bronchiogenic cyst. He was eventually able to free the cyst entirely and get it out in a collapsed state.

The microscopical sections from the wall of the cyst showed that it was lined with ciliated respiratory epithelium. Usually, cartilage is also to be found in the cyst wall. In the case under discussion we did not succeed in identifying cartilage, although there were old foci of calcification. This is not a rare location for bronchiogenic cysts. It is the same region in which tracheoesophageal fistulas

are found, and abnormal bronchial buds in this area are common and may develop into cysts of considerable size

DR AUB I do not believe that one can make that diagnosis before operation, do you?

DR MALLORY It would be no more than a guess

CASE 33462

PRESENTATION OF CASE

A thirty-five-year-old para II was admitted to the hospital because of abdominal pain

The patient's menstrual periods had begun about fourteen years before admission, occurring every twenty-eight days and lasting three to five days with no excessive bleeding until about seven years later, when she became pregnant. The pregnancy ended in a miscarriage, after considerable bleeding requiring a dilatation and curettage. She had two subsequent pregnancies six and three years before entry. With the last pregnancy she spent five months in bed to prevent a miscarriage and after delivery had excessive periods. Eight months prior to admission she had a dilatation and curettage and fifteen hours of radium treatment. Following this she developed a "pelvic abscess," which required five weeks of bed rest, penicillin and general supportive care and was finally drained rectally. Subsequent to the radium treatment the patient developed hot flashes, and the periods ceased. Injections prevented the hot flashes. After this the patient did well until four months before entry, when she began having pain almost constantly in both lower quadrants in the suprapubic region. The pain was sometimes relieved by urination or bowel movements. It was not referred, and had no association with food intake. Twelve hours prior to admission the patient had nausea and vomited once. She had been passing gas and had been anorexic for forty-eight hours prior to admission. She denied chills, fever or vaginal discharge and stated that she had recently lost about 12 pounds of weight.

Physical examination disclosed no enlargement of the heart, and the lungs were clear. In the right lower quadrant of the abdomen there was a hard tender mass about the size of an orange. Over this was a small olive-sized mass that rolled under the palpating finger and produced pain. A pelvic examination was not done.

The blood pressure was 130 systolic, 80 diastolic. Examination of the blood revealed a hemoglobin of 10 gm and a white-cell count of 10,000. The

of the abdomen revealed small in both the large and the small intestine, and a poorly defined area of indistinctness in the right pelvis. There were spots of calcification. The temperature,

pulse and respirations remained normal, and on the second hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR JOE V MEIGS This patient must have had some endocrine disturbance or an anatomic abnormality in the genital tract, such as a fibroid, to account for the multiple miscarriages. Following her last pregnancy she had abnormal menses and eight months before admission was treated with radium. It is impossible to guess the amount of radiation she received merely from the duration of the treatment, but it was obviously great enough to induce menopausal symptoms. I believe that it is not wise to use radium in a woman only thirty-five years old with a benign condition. At that age the patient would be far better off if operated on. The uterus, cervix and if necessary the tubes could be removed, but the ovaries should be left in place. Then the patient would not be condemned to the prolonged use of estrogens to combat menopausal symptoms. This patient was evidently treated with estrogens, since the symptoms were relieved by "injections." Again, we do not know the dosage or the duration of the parenteral treatment. It would be important to know if the treatment was continued up to the time of admission.

DR TRACY B MALLORY We have no further information about that.

DR MEIGS That radium therapy is not without danger and may produce serious consequences is demonstrated by this case, since a pelvic abscess developed after its use. This abscess may have been due to perforation of the uterus at the time of application of the radium, or it is possible that a pre-existing pelvic inflammatory disease flared up following the treatment. Certainly, the patient developed salpingitis with a pelvic peritonitis, which was drained through the rectum.

One can imagine that the most recent episode, which brought the patient to the hospital, represented another flare-up of the process. Again, she may have had enlargement of the uterus that was due to the accumulation of fluid above a cicatrix of the cervix. The estrogens, if continued, may have induced bleeding from the endometrium, and the blood could not escape through the cicatrized cervix, producing a hematometrium. That would cause pain.

The occasional relief of pain when the patient urinated or moved the bowels suggests inflammatory disease. However, she denied chills, fever or vaginal discharge. The white-cell count was normal, and the hemoglobin satisfactory. She had complained of anorexia and had recently lost 12 pounds in weight, but there was little evidence of any systemic reaction such as one would expect with inflammation.

I find it difficult to understand why no pelvic examination was done. It might have helped explain the confusing findings on abdominal palpation. The

mass described in the "right lower quadrant" could, I suppose, be an enlarged uterus full of blood, and the small tender mass a fibroid. Or the big mass itself could have been a fibroid, with a smaller one attached to it. The mass could equally well have been an ovary — either an ovarian abscess or simply a large cyst of the ovary. The x-ray examination does not help me. X-ray diagnosis can be incorrect in interpreting masses in the pelvis.

I believe that the best bet is that this young woman, who had a radiation-induced menopause, developed pelvic inflammation, was treated with estrogen for the hot flashes and then developed enlargement of the uterus without vaginal discharge, must have had a cicatrix of the cervix, with an accumulation of blood in the uterine cavity.

My diagnosis is radiation cicatrization of the cervix and hematometrium. My second choice is some sort of inflammatory mass associated with the right adnexa, representing a recurrence of the pelvic inflammatory disease.

CLINICAL DIAGNOSIS

Pelvic inflammatory disease?

DR. MEIGS'S DIAGNOSES

Cicatrix of cervix, post-radiation, with stenosis of cervical canal
Hematometrium

ANATOMICAL DIAGNOSES

Cicatrix of cervix, post-radiation, with stenosis of cervical canal
Hematometrium
Leiomyoma of uterus

PATHOLOGICAL DISCUSSION

DR. MALLORY: Dr. Meigs's prediction was correct. At operation an extensive pelvic peritonitis was found with dense adhesions binding all structures together, but no pockets of pus or evidence of acute inflammatory reaction. The uterus was large and soft, and there was a small fibroid on its surface. A hysterectomy was performed with some difficulty. When the uterus was opened the cervical canal was found to be completely obliterated, and the uterine cavity was full of blood, of which part was fresh and part obviously old.

THE DIETARY TREATMENT OF HYPERTENSION

THERE has been of late a considerable renewal of interest in the dietary treatment of essential hypertension. Doubtless from time immemorial and certainly from recorded medical history, much attention has been paid to diet in health and disease. A good deal of the benefit from diets has been found incidentally or empirically.

In 1866 Karell¹ introduced a diet for the effective treatment of edema and heart failure. It was a starvation ration consisting of only 800 cc of milk a day, and was limited in salt intake and fluids, as well as in calories. This diet is still, on occasion, used in the initial treatment of severe congestive heart failure.

In the early years of the twentieth century it was clearly proved that a low-sodium intake could clear edema due to congestive heart failure.² Hypertension was not specifically described in these cases, however, and it is doubtful if the blood pressures were recorded. When hypertension became well recognized as a cause of disease, dietary treatment of various sorts was instituted. The commonest of all kinds of such diet has been a simple reduction diet, low in calories, mostly because of restriction of fat and carbohydrates. Not infrequently there has also been, with a reduction of weight, a reduction of blood pressure, although such a relation has not always been found.

Moreover, during the early part of this century and even earlier, it had been customary to reduce the protein intake, largely by restriction of meat and eggs in patients with so-called "Bright's disease" with or without actual nephritis or congestive heart failure that might be secondary to hypertension. With a restriction of the amount of any food taken, but particularly with restriction of meat and eggs, the salt intake was coincidentally reduced and may well have had an important bearing on some of the good results noted, especially in patients with congestion.

In the 1920's, considerable interest was evoked in the use of a low intake of sodium chloride in the treatment of hypertension, with emphasis on the chloride. During those years there were controversies about the effects^{3, 4} but the reduction of sodium itself was apparently not so great at that time as recently.

A few years ago, Dr. Kempner, of Duke University, instituted the so-called "rice diet" (2000 calories, 20 gm of protein, 460 gm of carbohydrates, 5 gm of fat, 0.2 gm of sodium and 0.15 gm of chloride) in cases of nephritis and renal insufficiency. In the course of this study it was observed that the previously high blood pressure not infrequently fell to or toward normal figures. This led to the institution, three or four years ago, of the same diet for the treatment of hypertension per se. The success in some cases in relieving symptoms, in lowering the blood pressure and in the decrease or actual clearing up of evidence of serious hypertensive effects on heart and eyegrounds led to its adoption by Kemp-

ner⁴ more or less routinely in the treatment of hypertension. Slowly, knowledge of this therapy has spread from Durham, and the rice diet is being tried in other places, but with no extensive knowledge yet regarding the percentage of favorable results or the persistence of such favorable results over a prolonged period in the course of follow-up study. The percentage of favorable results in a series of 500 patients has just been calculated for a "seminar" to appear in the *American Journal of Medicine*. A lowering of the blood pressure was found in 181 (66 per cent) of the 271 patients with hypertensive vascular disease without evidence of renal excretory dysfunction (1 of the 90 so-called "negative patients" died), and in 129 (56 per cent) of the 229 patients with hypertensive vascular disease with renal involvement (25 of the 100 "negative patients" died after an average period of thirty-nine days).

The rice diet, based on rice itself largely because of its economy, availability and easily assimilated protein, also contains fruits and sugar, but no vegetables, meat, milk or salt. The first course of treatment consists of a strict diet, usually for four to twelve weeks, after which there is the addition of a potato or two a week and a small amount of meat. Very slowly, the diet is liberalized with the substitution of one third of vegetables for one third of the fruit and, finally, with the addition of more meat, but a full routine diet is not, as a rule, resumed. If symptoms recur or if the blood pressure rises, the original diet is started again. No adequate comparison has been made between the effects of the rice diet and those of Smithwick's lumbodorsal sympathectomy, which has proved its success in a certain percentage of hypertensive patients. Both therapeutic measures are radical and, it is hoped, may be replaced some day by simpler therapy.

Some investigators have believed that the benefit of the rice diet may be ascribed to its low sodium content, but as yet this theory has not been proved. The renewed interest in the therapy of hypertension by low-salt intake in the last few years has stimulated such dietary treatment in a number of different centers in the United States and Canada. It is still too early to determine what the ultimate results may be. Various degrees of sodium restriction are in-

volved, and various types of diets, with or without additional therapy, are being tried.

It should be possible after careful studies during the next two or three years to learn what diet or diets may be useful in hypertension and how they work — whether by restriction of sodium, protein and fat, including cholesterol,⁷ by combination of such restrictions or for other reasons. It is necessary by detailed studies and by careful follow-up to work out careful answers to the questions that have been propounded.

MADAME PRESIDENT

Boston claims with pride the distinction of being the birthplace and family home of the first woman president of the American Public Health Association, Dr. Martha May Eliot, who assumed that office on October 9, 1947.

Dr. Eliot is a member of a family that has consistently made its contribution to the public welfare. Her grandfather, William Greenleaf Eliot, founded Washington University in St. Louis, her father, Dr. Christopher R. Eliot was a clergyman of Dorchester. Her brother, the Reverend Dr. Frederick May Eliot of Cambridge is president of the American Unitarian Association; her sister, Dr. Abigail Adams Eliot is director of the Nursery Training School of Boston. The late Charles W. Eliot, former president of Harvard University, was a second cousin of the Reverend Dr. Christopher R. Eliot. Charles W. Eliot's son, the Reverend Dr. Samuel Eliot, preceded Dr. Frederick M. Eliot as president of the American Unitarian Association. Certainly public service has become a heritage and a tradition in the Eliot family.

Dr. Eliot was born in Dorchester on April 7, 1891. She attended the Winsor School and Radcliffe College, from which she graduated in 1913. During the

year after leaving college she worked in the Social Service Department of the Massachusetts General Hospital, in the Children's Cardiac Clinic. In 1918 she received her degree in medicine from Johns Hopkins University School of Medicine after which she interned at the Peter Bent Brigham Hospital.

She became in 1921 the first woman resident physician at the New Haven Hospital, with a teaching position at Yale University School of Medicine. In these early years she made a noteworthy study on rickets for the United States Children's Bureau, and she shortly became a member of the bureau's staff. In 1934 she became assistant chief of the bureau, and in 1941 associate chief. In that year she was sent by the United States Government on a military mission to England to study the impact of war on children under conditions of bombing and evacuation. During the summer of 1947 she was on the staff of the International Children's Emergency Fund Committee of the United Nations, in which capacity she made two trips to eastern Europe, penetrating even the "iron curtain" in the interest of the children of those countries. She is particularly well known as the author of the Emergency Maternal and Infant Care program.

Dr. Eliot has stood firmly for governmental support of health services for all the people—one of the controversial subjects of the day. Whichever side of the argument her professional colleagues may favor, they must respect her opinions and honor her achievements. She has earned her positions on the health councils of the land.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

REPATRIATION OF WORLD WAR II DECEASED

The Department of Public Health has informed local boards of health regarding the plans and regulations of shipment of World War II deceased.

Upon arrival of the remains in the local community where they are to be buried, the next of kin will arrange with the proper authorities for the issuance of the burial permit. The local board of health of the community wherein burial is to be made will issue a burial permit covering the remains of the World War II dead to any licensed funeral director in the state upon presentation of the decedent's name, rank and serial number, which is stenciled on the end of the outside shipping case, and the basic health permit number as indicated on the basic health permit marker, which is attached

to the end of the shipping case. No Massachusetts Standard Certificate of Death Form R-301 need be filed except for persons who died in the service abroad since the end of hostilities. In such cases a complete death certificate will be returned with the transit permit.

In filling out the burial permit, the phrase "World War II Deceased" will be entered under the cause of death.

Additional routine information as required should be requested of the funeral director, such as residence of next of kin and plan of interment.

The following rule was adopted by the Board of Registration in Embalming and Funeral Directing at its meeting held on September 26, 1947:

Rule 46-A—No casket, box or other container in which a body that has been disinterred and shipped to this country from foreign soil, shall be opened before burial of such body in the Commonwealth.

The outside shipping case is not included in the above rule.

CANCER INSTITUTE

A cancer institute will be held in Boston from November 16 to 21, inclusive, under the joint sponsorship of the Massachusetts Department of Public Health, Harvard School of Public Health, American Cancer Society (Massachusetts Division, Incorporated), Massachusetts Medical Society (Committee on Cancer), Massachusetts Dental Society and Boston Health League.

A public meeting, sponsored by the Harvard School of Public Health, will be held in the amphitheater of Building E, Harvard Medical School, at 3 30 p m on Sunday, November 16. A conference for state-aided cancer-clinic workers and a meeting for medical social workers, nurses and similar personnel will be held at the Red Cross Chapter House, 17 Gloucester Street, from 10 30 a m to 4 00 p m on Monday, November 17. A clinic for members of the Massachusetts Dental Society will be conducted at the Palmer Memorial Hospital, 195 Pilgrim Road, at 2 00 p m, with a luncheon meeting of cancer-control committees at Vanderbilt Hall, Harvard Medical School, at 1 30 p m on Tuesday, November 18. On Wednesday, November 19, from 10 00 a m to 4 30 p m, a meeting for state-aided cancer-clinic staffs will be held in Amphitheater 3A of the White Building, Massachusetts General Hospital. The American Cancer Society (Massachusetts Division, Incorporated) will present a radio program on Thursday, November 20. A meeting of medical social workers, nurses and similar personnel will be held in the auditorium at 100 Nashua Street from 10 15 a m to 4 00 p m on Friday, November 21.

ROBERT N NYE MEMORIAL FUND

The American Cancer Society, Incorporated (Massachusetts Division), announces that the Robert N Nye Memorial Fund is in excess of \$2245.

ROBERT NASON NYE

(1892-1947)

Robert Nason Nye was born in Springfield, Massachusetts, on June 3, 1892, the son of George Nye, Jr., and Mabel Francis (Nason) Nye. Entering Harvard College in the fall of 1910 he qualified for his degree *cum laude* in 1913. He spent the following year at the Harvard Medical School and then went into business. He returned a year later, received his degree *cum laude* in February, 1918,

and enrolled in the Medical Reserve Corps, although he was never called to active duty, after a few months in the Pathology Laboratory of the Boston City Hospital, he served a medical internship at the Massachusetts General Hospital. He subsequently worked for a year in the Medical Research Laboratory of the Hospital, returning in 1920 to the Boston City Hospital as assistant pathologist. In 1922 he was appointed assistant director of the Antitoxin and Vaccine Laboratory of the Massachusetts Department of Public Health, resigning to become assistant physician to the new Thorndike Memorial Laboratory at the Boston City Hospital. He became associate physician to the Laboratory in 1929. He had been assistant professor of bacteriology and immunology at the Harvard Medical School since 1942.

Meanwhile, in 1937, he had turned his talents in a new direction, succeeding the late Dr. Walter P. Bowers as managing editor of the *New England Journal of Medicine*. The capable leadership that he brought to the *Journal* has been largely responsible for its continued progress and the maintenance of its high standards.

He became a member of the Committee on Information, Division of Medical Sciences of the National Research Council in 1940, and during the war was a member of the Committee on Information of the Procurement and Assignment Service of the War Manpower Commission.

Dr. Nye was an editor of *War Medicine*, recently published by the American Medical Association,

a councilor of the Massachusetts Medical Society, a trustee and treasurer of the Boston Medical Library, a councilor of the Harvard Medical Alumni Association and director at large of the Massachusetts Tuberculosis Association. He was a member of the American Society for Clinical Investigation, the American Association of Pathologists and Bacteriologists, the American Association of Immunologists, the American Academy for the Advancement of Science and the Society of Experimental Biology and Medicine.

In 1917 he married Katherine Blake Lincoln, of Springfield, who survives him with their two children, Mrs. William Caldwell Coleman, Jr., of Baltimore, and George Nye, and two grandchildren, William Caldwell Coleman, III, and Robert Nason Nye, II.

Here are his achievements and his record — the record of one who did well that to which he set himself. In work or in play he did not put his hand to a task or his mind to a problem without mastering it. Whether in keeping bees or in luring a salmon or in turning from the exacting science of bacteriology to the exacting duty of editing and managing a leading journal of medicine, he did the thing in hand superlatively well.

We shall remember him for his varied contributions to the changing pattern of medical science and literature and sociology. We shall remember him with deeper feeling as an ardent lover of life with a peculiar sensitiveness to the muted strings of nature — among his garden flowers or looking for the first hepatica bloom on his wooded island, or stopping on the trail to identify a warbler that had dallied in its northern flight or casting a fly over a ripple on the lake he loved so well. The goal of life was in the living of it.

Knowing that Nature never did betray
The heart that loved her; 'tis her privilege
Through all the years of this our life to lead
From joy to joy

MISCELLANY

PRIZE SUBSCRIPTION

The prize subscription offered by the *New England Journal of Medicine* for the best undergraduate contribution to the *Tufts Medical Journal* has been awarded to William H. Waugh for his paper "The Sites and Mechanism of Plasma Globulin Formation," which appeared in the June, 1947, issue. The paper "Some Achievements of the Public Health Laboratory," by Miriam Manning received honorable mention, it appeared in the December, 1946, issue. According to custom, these students will be given a two-year and a one-year subscription to the *Journal*, respectively.

NOTES

Dr Robert E. Gross, surgeon-in-chief of the Children's Hospital, Boston, and William E. Ladd Professor of Child Surgery, Harvard Medical School, was awarded the Matas Medal at New Orleans on October 3, 1947.

In 1933, under the will of Violet Hart, a fund was established for the purpose of awarding a medal from time to time to a surgeon who had contributed to the advance of surgery of the blood vessels. It is named in honor of Dr. Rudolph Matas, of New Orleans, a pioneer surgeon in this field. Since 1933 there have been four awards to Dr. Mont Reid, of Cincinnati, Dr. DeSantos, of Portugal, Dr. Daniel Elkin, of Atlanta, and, in 1947, to Dr. Gross.

The medical profession of Boston takes pride in this tangible recognition of the abilities of one of its fellow members.

Dr. Kendall Emerson, managing director of the National Tuberculosis Association since 1928, has announced his resignation, effective January 1, 1948. He will be succeeded by Dr. James E. Perkins, deputy commissioner, Department of Health, State of New York.

BOOK REVIEWS

Anesthesia in General Practice. By Stuart C. Cullen, M.D. 8°, cloth, 260 pp., with 36 illustrations and 4 tables. Chicago: The Year Book Publishers, Inc., 1946. \$3.50.

This book represents a necessary step in the development of literature on anesthesiology. It is a good textbook for students, and as such fills a pressing need. The discussion of anesthetic agents, methods of administration, drugs, pre-operative medication and postoperative care of the patient is not exhaustive but is clearly and concisely outlined. The chapters on shock, oxygen therapy and explosion hazards are treated in their proper relation to the practice of anesthesiology. The cartoons presented seem somewhat juvenile at first glance. Actually, they are effective in focusing the attention of the student on important principles of diagnosis and treatment of drug reaction and oxygen lack. This book is a straightforward presentation of basic facts in the practice of anesthesiology.

Personality of the Preschool Child. The child's search for his self. By Werner Wolff, 8°, cloth, 341 pp., with 118 illustrations. New York: Grune and Stratton, 1946. \$5.00.

This excellent book is based on the idea that, although detailed studies of the child's overt behavior are available, an attempt should be made to study "the hidden forces and motivations" of such behavior. The task was to design experiments to explore the spontaneous verbal, graphic and dramatic expressions of children and thus to gain a unifying concept. The approach is called "experimental depth psychology." The author thinks that the young child's action can be interpreted as a continuous search for his self. It is a fundamental fact that the child's world is different from that of the adult and that the child cannot be understood in any terms taken from adult psychology. The young child lacks all the experience of an adult, who fills in continuously the gaps in his own experience by pieces of knowledge that he has acquired from his surroundings. The preschool child, with little or no knowledge and facing constantly new experiences, has not yet an understanding of the value of the

various items he encounters. The child is therefore forced to overbridge the gaps by imaginary interpretations drawn from fantasy rather than from experience.

The book is divided into three parts. The first discusses several aspects of the child's mind, conditions and social activities and his concept of reality. The second attempts a construction of the child's personality through the reflection of his various activities and reactions. In this section, play and drawings are freely used for the exploration of the preschool child's world. The only criticism that could be attached to this otherwise interesting study is that the author relies in his interpretations too much on the expressions of the child himself or on his own interpretation of what he thinks the child meant. The third section discusses the principle of children's art, as well as the child and the adult and methods in child psychology.

By virtue of the fact that the author emphasizes in the beginning the differences between the adult's and the child's world, some of the interpretations appear not too convincing, and the author draws too heavily on other sources of experience like psychoanalysis to achieve the goal of a unifying interpretation of the child's personality—a knowledge that the author's own material cannot provide in every direction.

The book, although written primarily for psychologists and not psychiatrists, contains a great wealth of material, and will prove of benefit to any pediatrician or psychiatrist.

The Principles and Practice of Medicine. Originally written by William Osler, M.D., F.R.C.P. Designed for the use of practitioners and students of medicine. By Henry A. Christian, M.D., LL.D., (Hon.) Sc.D., Hon. F.R.C.P. (Can). Sixteenth edition. 8° cloth, 1539 pp. New York: D. Appleton-Century Company, Inc. 1947. \$10.00.

Dr. Osler published his monumental textbook in 1892 and was solely responsible for the first seven editions. In 1916 Dr. Thomas McCrae became a joint author, and in 1919 after Dr. Osler's death he carried the work through the twelfth edition, published in 1935. Dr. Christian assumed the authorship with the thirteenth edition in 1938 and has continued to revise the succeeding editions. He inaugurated an innovation by appending lists of selected references to each subject and thus enabling the reader to follow up any given subject. These references include the literature of 1945.

The new edition has been thoroughly revised to bring it up to date, resulting in the complete resetting of more than nine hundred pages.

The book has had a remarkable publishing history. At least eighty-four separate printings have been issued simultaneously in America and England through the fifteenth edition. In recent years the publishers have indicated the printings by a numeral found at the end of the index. Unfortunately, in the sixteenth edition the system has reverted to number one, indicating the first printing of this edition. The binding has been varied. The first four editions were issued in four styles, two in leather and two in full cloth, and in four different colors. Editions five to seven were bound in brown half leather and full red cloth. With the thirteenth printing of the eighth edition the binding was standardized in one style of full red cloth that has been continued to date. The first printing of the first edition is identified by the date of the advertising pages, the misprinting of "Gorgias" as "Georgias" in the quotation from Plato and the lettering on the backstrip (the edition number was not printed on the backstrip of editions one to seven). The first English printing appeared both with and without the Plato error. The fourth English edition was pirated, resulting in two issues by Pentland and by Kimpton. The work has been translated into three Chinese editions, as well as into French, German, Spanish and, in 1945, Portuguese.

The Boston Medical Library has a unique collection of editions of this textbook, originally begun by Dr. Henry R. Viets and continued by the Library. It numbers to date one hundred different printings in the various bindings of the American edition, as well as the English editions, all the translations and the first American and English printings. Dr. James C. Carr has prefixed to the sixteenth edition a short history of medicine (1892-1947) as told in the sixteen editions.

The popularity of the book is attested by its numerous printings over a period of fifty-five years and the fact that the

publishers are making an initial printing of this 1947 edition larger than that of any of their popular texts for the last twenty five years. The material is well organized and emphasizes symptomatology, diagnosis and treatment. The printing is well done with a good type on light paper resulting in a comparatively light volume for the number of pages. A remarkable comprehensive index of 147 pages concludes the book. It is hoped that with the seventeenth edition wider margins will be restored to the pages.

The book is an ideal reference text for the busy practitioner and should be in all medical libraries.

The Ranks of Death. A medical history of the conquest of America. By P. M. Ashburn, M.D. Edited by Frank D. Ashburn. 8", cloth, 298 pp. New York: Coward-McCann, Inc., 1947. \$5.00.

The manuscript of this posthumous volume, by the well known author of *The Elements of Military Hygiene and A History of the Medical Department of the United States Army*, was found among his papers and prepared for publication with an appropriate preface by his son. It presents a medical history of the conquest of America particularly the part played on both sides by diseases including famine, scurvy, smallpox, typhus, measles, malaria, yellow fever, tuberculosis, pneumonia, diphtheria, dysentery, typhoid fever and syphilis. In general these auxiliaries indicated more casualties on the aborigines than on the invaders whose resistance and intelligence were superior. In his epilogue, the author suggests that the race can best keep well by acquiring immunity.

This is an exceedingly valuable volume, not only in itself but also as a source for future students and writers. A large amount of technical material allied with the text is collected in three appendices where it is easily available for reference.

Studies and Essays in the History of Science and Learning Offered in Homage to George Sarton on the Occasion of his Sixtieth Birthday 31 August 1944. Edited by M. F. Ashley Montagu. Ph.D. 8", cloth 596 pp. with illustrations and portrait. New York: Henry Schuman 1947. \$12.00.

George Sarton, the distinguished professor of the History of Science at Harvard University and author of an indispensable tool for workers in the field of science and medicine, his *Introduction to the History of Science* attained his sixtieth birthday on August 31, 1944. The present volume, whose publication was much delayed by the war, was presented to him by his friends in manuscript form on that occasion. The contents reflect the wide basis on which the history of science rests, for among the twenty seven essays written in homage to Sarton the following topics are given consideration: Vesalius on bloodletting; Da Vinci as a military engineer; linked heredity; positivism; ethiogenesis; Galileo's Platonism; transfinite numbers; Babylonian astronomy; Chinese grammar; maps of the Missouri River; and public bureaucracy and a biography of George Green the physicist. The interest of everyone with scientific curiosity should be stirred by one or more of the scholarly and informative papers in this exceptionally pleasing volume. Not the least important is the all too brief biographical sketch of the modest master of the subject, which lets in a little more light on his complex career transplanted in April 1915 from a war torn Belgium to what at first was a cold and unappreciative America. Slowly his outstanding rank in history and science was appreciated, and in 1940 among many other honors, Harvard made him a full professor.

The volume is well edited and well printed. An excellent portrait of Sarton serves as a frontispiece. The publisher has shown great taste in the format. The only drawback is the price, made necessary by the times and in spite of "benefactors" which may well serve to keep the book out of deserving hands.

The Self You Have to Live With. By Winfred R. Bode. Revised edition. 8", cloth, 254 pp. Philadelphia: J. B. Lippincott Co., 1947. \$2.00.

The author of this book assisted Dr. Joseph H. Pratt in building up the Thought Control Clinic of the Boston Dispensary. For years he has worked with patients referred to that clinic by doctors in various parts of New England

during which time he has witnessed and helped the development of group psychotherapy in a unique way.

This book is one of the fundamental chapters from his experience. It contains common-sense points of view and ideas that he has used in dealing with patients who have expressed a wish to help themselves by psychologic means. It is not so much a profound as it is a practical book. The ideas are an interesting rephrasing of old truths in a form that is handy for clinical use, rather than new discoveries. The volume belongs with books that are valuable as a form of self help and as such can be considered a contribution to bibliotherapy.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Office Immunology including Allergy. A guide for the practitioner. Edited by Marion B. Sulzberger, M.D., professor of clinical dermatology and syphilology and director, New York Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital and Rudolf L. Baer, M.D., instructor in dermatology and syphilology, New York Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital. 8", cloth, 420 pp. Chicago: Year Book Publishers, Incorporated 1947. \$6.50.

This volume, the joint work of six physicians, is published as one of the *General Practice Manuals*. It is principally concerned with the infectious diseases and dermatologic and other allergies. Emphasis is placed on diagnosis, treatment and preventive inoculation. Drug eruption, eczematous contact type allergic dermatitis and patch testing are fully discussed. The manual is written for the practicing physician and endeavors to assemble in one volume the essential material now scattered through many volumes.

Medical Aspects of Growing Old. By A. T. Todd, M.B. (Edin.), M.R.C.P. (Lond.) honorary physician, Bristol Royal Infirmary. 8", cloth, 164 pp. with 15 illustrations. Bristol: John Wright and Sons Ltd. 1946.

This manual, which has been written for the laity as well as for physicians, has been kept as simple as possible. The first part treats of mentality, physiology of the digestive tract and diet, retirement and the use of leisure time, exercise and sleep. These chapters are followed by a discussion of conditions met with in the aged: constipation, cardiovascular disturbances, blood pressure, emphysema and genitourinary troubles in both men and women. There are also chapters on the care of the nose, skin, hair and feet. The material is well organized and well written. The publishing is excellent. The advice given is sensible and the manual should prove valuable to those interested in the medical care of the aged.

Year Book of Endocrinology, Metabolism and Nutrition for 1946. Endocrinology edited by Willard O. Thompson, M.D., clinical professor of medicine, University of Illinois College of Medicine, attending physician (Senior Staff), Hennrich Hospital and attending physician, Grant Hospital of Chicago. Metabolism and Nutrition edited by Tom D. Spies, M.M., associate professor of medicine, University of Cincinnati School of Medicine and director, Nutritional Clinic, Hillman Hospital, Birmingham, Alabama. 12", cloth, 573 pp., with 85 illustrations. Chicago: Year Book Publishers, Incorporated 1947. \$3.75.

For twelve years the subject of endocrinology has been published as a part of the *Year Book of Neurology, Psychiatry and Endocrinology*. For 1946 it appears as a new year book associated with metabolism and nutrition. The volume comprises abstracts of important articles printed in English in various periodicals for 1946. Indexes of subjects and authors conclude the volume, which is well published in every way. It should prove useful to persons interested in the subjects discussed and desiring to keep abreast of the current literature.

Microbial Antagonisms and Antibiotic Substances By Selman A Waksman, M S, D Sc, Ph D, professor of microbiology, Rutgers University, and microbiologist, New Jersey Agricultural Experiment Station Revised edition 8°, cloth, 415 pp, with 33 figures New York The Commonwealth Fund, 1947 \$4.00

Since the completion of the text of the first edition of this book in 1945, great advances have been made in the field of antibiotics. Penicillin and streptomycin have become important chemotherapeutic agents. The text has been thoroughly revised to bring the subject up to date, and much new material has been added. The bibliography comprising 1053 citations has been revised by the omission of many of the historical items contained in the first edition and by the addition of references to the literature to 1946. The book should be in all medical libraries and in the libraries of all persons interested in the subject.

NOTICES

Dr Robert F Dine announces the opening of an office for the practice of orthopedic surgery at 483 Beacon Street, Boston, and for the practice of bone and joint surgery at 741 Main Street, Waltham

Dr Nathan Louis announces the removal of his office to 171 Bay State Road, Boston

Dr James W Sever announces the removal of his office to 330 Dartmouth Street, Boston

Dr Richard C Webster announces the removal of his office for the practice of plastic and reconstructive surgery to 1101 Beacon Street, Brookline.

JOSEPH H PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston
Lecture Hall, 9-10 a m

MEDICAL CONFERENCE PROGRAM

Friday, November 14 — Prolonging the Action of Penicillin

Dr Albert O Seeler

Wednesday, November 19 — Glycogen Storage Disease

Dr Richard Wagner

Friday, November 21 — The Evaluation of Drugs for the Relief of Bronchial Asthma

Dr Maurice S Segal

Wednesday, November 26 — The Discovery of Insulin

Dr Joseph H Pratt

Friday, November 28 — Studies of Certain Metabolic Disturbances Carried Out with the Aid of Isotopes

Dr DeWitt Stetten

On Tuesday and Thursday mornings from 9 00 to 10 00 Dr S J Thannhauser will give medical clinics on hospital cases. On Friday afternoons from 2 00 to 4 00 therapeutic conferences will be held with round-table discussion, Dr R P McCombs, Moderator. On the second and fourth Friday afternoons of each month, Dr Merrill Sosman will conduct x-ray conferences from 4 00 to 6 00. On Saturday mornings from 9 00 to 10 00, clinics will be given by Dr William Dameshek. Medical rounds are conducted each weekday except Saturday by members of the Staff from 12 00 to 1 00.

All exercises are open to the medical profession

GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society will be held in the auditorium of the Beth Israel Hospital on Tuesday, November 18, at 8 15 p m. A symposium on cancer will be presented, with Dr Joseph C Aub as chairman.

PROGRAM

The Use of the Nitrogen Mustards and Urethane in the Treatment of Neoplastic Disease Dr David A Karnofsky

Studies in the Chemotherapy of Cancer Dr Arnold Seligman

Endocrine Therapy of Carcinoma of the Breast Dr Ira T Nathanson

Stilbamidine in the Therapy of Multiple Myeloma Dr Bernard Jacobson

SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculous Association, 554 Columbus Avenue, Boston, on Tuesday, November 18, at 12 noon. Dr Charles P Emerson will speak on "Leukemias and Lymphomas."

Physicians are cordially invited to attend

CUTTER LECTURE

The Cutter Lecture on Preventive Medicine, initiated in 1912, will be given by Dr Haven Emerson, Emeritus Professor of Public Health Practice, Columbia University School of Public Health, on Monday, November 24, at 5 p m, in the Amphitheater of Building D of the Harvard Medical School. His subject will be "Whither the Pegasus of Public Health?"

The medical profession, medical and public-health students and others interested are cordially invited to attend

RADIOLOGICAL SOCIETY OF NORTH AMERICA

The thirty-third annual meeting of the Radiological Society of North America will be held at the Hotel Statler, Boston, from November 30 to December 5, inclusive. Symposia on the economics of medicine, pediatric roentgenology and radioactive iodine will be held on various days of the meeting, and numerous papers concerning the latest advances in x-ray diagnosis and treatment will be presented by members of the society. Dr Douglas Quick, of New York City, will deliver the Carman Lecture at 8 p m on Tuesday, December 2.

More than 800 members of the society are expected to attend the meeting. The scientific program and exhibits give promise of being of great interest. The "refresher courses" will be given as usual. The commercial exhibits will embrace all the recent and projected developments in diagnostic and therapeutic apparatus. An interesting ladies' program has been planned.

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Massachusetts General Hospital on Monday, December 1, at 8 15 p m. Dr Paul D White will preside.

PROGRAM

Announcements by the president, Dr Howard B Sprague. The Treatment of Intractable Paroxysmal Tachycardia by Sympathetic Block Drs Edward F Bland and J C White

Coronary Arteriovenous Aneurysm A rare anomaly Dr Oglesby Paul, Richard H Sweet and Paul D White.

A Case of Rheumatic Heart Disease with Periodic Arterial Embolism Ambulatory treatment with dicumarol.

Dr Howard B Sprague and Robert P Jacobsen, Ph D

Neurocirculatory Asthenia Drs Mandel E Cohen, Edwin O Wheeler and Paul D White

Phonocardiography and Electrolymography Drs Howard B Sprague and Bertrand Wells

Unipolar Limb Leads Dr Conger Williams

Interested physicians and medical students are cordially invited to attend

SUFFOLK DISTRICT MEDICAL SOCIETY

A stated meeting of the Suffolk District Medical Society will be held at the Boston Medical Library on Tuesday, December 9, at 4 30 p m.

OCCUPATIONAL DERMATOSES (ERGODERMATOSES)*

Diagnosis, Disability and Treatment

JOHN G. DOWNING, M.D.†

BOSTON

TWENTY minutes is rather a brief period in which to discuss the large field of industrial dermatoses, but a few thoughts resulting from twenty-five years experience may be of interest. During that time many thousands of workers with cutaneous disturbances have been examined, key industrial plants have been inspected, and lectures have been given to workers, foremen and insurers. Most of the cases considered industrial have been treated, therefore, considerable experience has been gained by trial and error. No set rules have ever been established for the treatment of such dermatoses. The industrial patient must be treated until he is well, there is no reason why he should not recover, because all true occupational dermatoses are curable.

In Massachusetts in 1922 little was known about the effects of industrial exposures, but with the rapid introduction of new chemicals, insurers and industrialists soon learned that the resulting cutaneous disturbances were numerous and expensive. Industry in the Commonwealth has changed in the last twenty-five years. Old industries are gone, and new ones have been installed. Formerly, the leather industry was responsible for a large amount of workers' disability due to occupational dermatoses, later, the rubber industry contributed quite a few cases. The former moved away, and the latter cleaned house. As a result of prophylactic measures, industries formerly notorious for causing dermatoses now have only an occasional worker affected.

The first cases of dermatitis from work with plastics were seen in a small plant in a large field, it is now such a large plant that the field seems small. When this plant was first visited, it was dusty and reeked of fumes. Finished fabricated plastics, being inert, do not cause dermatoses, but the processing of the raw materials produces a considerable number of cutaneous reactions. There is a dangerous

combination of powders, liquids and gases. Although plastics have been made as long as clay has been known, the use of resins resulting from the reaction of phenol and formaldehyde and similar reactions is only thirty years old. The pruritic eruption due to mechanical irritation from the powders has been fairly well eliminated by improved personal hygiene, better washing facilities and the use of protective creams. Education has eliminated skin conditions caused by the careless handling of liquids, which ranged from simple follicular eruptions to severe burns. Lastly, proper sanitation has eradicated not only the helmet-like type of dermatitis on the exposed areas of the skin caused by fumes but also the fine papular eruption resembling prickly heat that appeared on the covered areas, especially in warm weather, owing to penetration through the clothing. There was a constant change of personnel, for whereas many became desensitized, others had to give up this work. Those now affected are new and inexperienced workers.

Lectures accomplish a great deal, but money talks more successfully. Insurers, recognizing the bad risks, drop these policies and the next insurer raises the premium. A worker with an occupational rash is an expensive liability, especially in these days of high-cost hospitalization. Apart from the loss of time and wages of the employee, the compensation and medical expenses may amount to several thousand dollars. A mild eruption may cost at least two or three hundred dollars.

The introduction of patch tests was hailed as the solution to this puzzle (Fig. 1). Insurers began to insist on them, commissioners requested them, and patients consented to submit to them. After a decade of enthusiasm, however, patch tests have lost much of their popularity, owing to the number of false or severe reactions (Fig. 2). They are now relegated to their proper use—that is, only when indicated. They have their fallacies and limitations, but with a carefully taken history showing definite exposure to the test material, and with a characteris-

*Presented at the annual meeting of the Massachusetts Medical Society, Boston, May 20, 1947.

†Professor of dermatology, Boston University School of Medicine and Tufts College Medical School.

tic test eruption, a positive finding followed by the prevention of further exposures should result in a cure¹

Years ago most workers attributed every eruption to their work. Skilled employes soon realized that alleged industrial hypersensitivities were disastrous, physically and financially, and demanded proof of the causative factor. The physician became more

FIGURE 1 Method of Patch Testing¹

A piece of linen is moistened with the test substance and covered with Scotch tape that is rimmed with narrow adhesive

careful in his diagnosis of an occupational dermatitis, for the well paid artisan is apt to resent any loss of pay when it is proved that his eruption is not due to his work but is constitutional in origin or is due to contacts at home, especially when industrial commissioners so rule against him. With the recent increase in wages, workers became suspicious of snap diagnoses, and it is amazing how many continued to work despite their occupational eruption and were relieved without loss of time.

Despite the tremendous increase in industrial activities during World War II, the increase in dermatoses was not excessive in this part of the country, except in the incidence of infection due to cutting

oils. The increase occurred for the most part in plants transformed overnight into machine shops. The incidence of claims for industrial dermatoses is an excellent index of industrial productivity. For the past two months there have been more claims than in any two months when wartime activities were at their height.

DIAGNOSIS

What establishes the diagnosis of an occupational dermatosis? In 1939 the Committee on Industrial Dermatoses of the American Medical Association² adopted the following definition: "An occupational dermatosis is a pathological condition of the skin for which occupational exposure can be shown to be the major causal or contributory factor." The same committee submitted the following criteria, which usually apply in the majority of cases of occupational dermatoses:

The dermatologic diagnosis is that of a dermatosis in which the role of an occupational causal (major or contributory) factor has at some previous time been established beyond reasonable doubt.

The patient has been working in contact with an agent known to have produced similar changes in the skin.

The time relation between exposure to the agent and the onset of the dermatosis is correct for that particular agent and that particular abnormality of the skin.

The site of the onset of the cutaneous disease and the site of maximum involvement are consistent with the site of maximum exposure.

The lesions present are consistent with those known to have followed the reputed exposure or trauma.

The patient is employed in an occupation in which similar cases have previously occurred.

Some of the fellow workers using the same agent are known by the examiner to have similar manifestations from the same cause.

So far as the examiner can ascertain there has been no exposure outside the occupation that can be implicated.

If the diagnosis is dermatitis, the following items are important: attacks occurring after exposure to an agent, followed by improvement and clearing after cessation of exposure, constitute most convincing evidence of the occupational factor as a cause, and the results of patch tests performed and interpreted by competent dermatologists corroborate the history and the examination in the majority of cases.

These criteria, however, are rather complicated and do not apply to cases in which there is aggravation of an existing cutaneous disease by industrial exposure. Nor do they apply to the large number

of cases in which the disabling eruption has resulted from treatment by the plant physician or nurse with a sensitizing medicament or has been caused by overtreatment

MEDICOLEGAL ASPECTS

In Massachusetts the legal definition of occupational dermatosis seems more clear-cut. It is any injury, damage, harm or disease of the skin that arises out of and in the course of employment.* Such an injury is compensable if it causes incapacity

Cases of occupational dermatoses are so complicated that the Massachusetts Industrial Accident Board will not accept an opinion unless it is expressed by a duly qualified physician. What makes these decisions so difficult? It is because few have the training that enables them to assemble all the parts and solve the problem. A physician must have dermatologic training to distinguish between the occupational and the nonoccupational dermatoses. In reviewing many thousands of cases of workers presenting claims, I found about 40 per cent to be

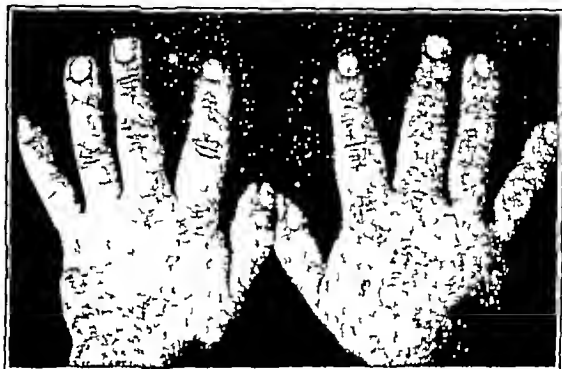

FIGURE 2. Case of J. T., a Candy Maker (Dermatitis from Contact with Cinnamon Oil)

The patch test resulted in a generalized dermatitis

and takes away a worker's ability to earn wages. Disease is not compensable unless it arises from an injury, and although dermatitis is considered a disease, definite injury must be established before a claim is accepted. These facts are simple but are misinterpreted, not only by the general practitioner but also by the dermatologist. A recent article written by a dermatologist stated that miliaria was not considered occupational if the weather was hot (Miliaria is an acute affection of the sweat glands that occurs in many persons in hot weather, regardless of whether or not they work). A new industrial commissioner dreads a case of dermatitis, and few private lawyers have any understanding of the Compensation Act or of the court decisions regarding it. May a plaintiff have lost his claim except for a sympathetic commissioner? These officials are admittedly slightly partial to the employee, and perhaps justly so. To the insurer and its representatives, either lawyers or physicians, it is just another case, the loss of which will not in any way change their routine. To the injured worker it is a tragic, all-absorbing controversy, the solution of which may determine his future and that of his family.

nonindustrial, comparatively few of these opinions have been disputed. Correct dermatologic diagnoses save employers, insurers and employees many thousands of dollars. A knowledge of occupational exposures is essential, including the chemicals used and the processes involving their use. A knowledge of the sanitary conditions in a particular plant is helpful. For example, fungous infection of the feet is not considered industrial, but, if a man is constantly working on a wet or damp floor so that his shoes and socks are always wet, an ideal condition is produced for the growth of yeast and fungi and could be a precipitating factor in a disability that later results from this infection.

Thorough examination of the claimant is essential. The sites first affected and the characteristics of the eruption should establish a definite diagnosis of an occupational dermatosis. These facts are few, but each one has its own importance in the expression of an opinion. The physician needs no vast knowledge of chemistry or sanitation to gather all his data, because on request the insurer as a rule will supply this information, if not, the various state agencies are willing to assist him.

There are a large number of cases in which the worker acquires a superficial injury of the skin, such as a paper cut, abrasion or friction burn, and later suffers a pyogenic infection at this site, showing a sharply outlined vesicular and pustular eruption that is resistant to treatment and subject to frequent relapses. These cases are often mislabeled "fungous infection" owing to failure to obtain a history of injury or cultural studies, and the worker is refused compensation. The largest group, however, comprises patients overtreated or treated with medication to which they have a hypersensitivity. This medication was formerly a mercury compound, later the sulfonamide group, and next penicillin, and I have recently seen 2 cases resulting from the use of Furacin. These drugs should not be em-

alkalies, metals, salts, essential oils, solvents and miscellaneous substances.⁵ In this large group of cases, the history should reveal the causative factor, because patch tests are unnecessary. Primary irritants should not be used in patch testing. Again, most of the workers suffering from the above conditions can continue to work unless the eruption is severe, when it has disappeared, there is no reason why they should not return to their previous occupation.

It is essential to distinguish between primary skin irritants and sensitizers, frequently called "aller-

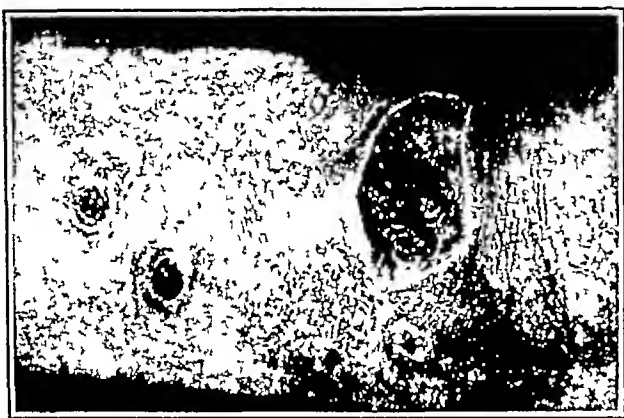

FIGURE 3 Case of S D, a Leather Seasoner (Chromic Acid Burns)

The lesions (seen in tanners, masons and plasterers) show an elevated rim of whitish-gray skin with a central dark ulceration resembling a pigeon's eye, and hence called "pigeonneau"

ployed in occupational dermatoses unless there is infection, and then with caution and only until the secondary infection is relieved, when bland medication should be substituted.

HYPERSENSITIVITY

The majority of true occupational dermatoses are due to primary skin irritants. In 1936 the committee mentioned above defined a primary irritant as follows: when a substance in a given concentration, in a given vehicle and in a given manner and length of exposure produces a clinically manifested irritation on the skin of a majority of persons not previously sensitized to that substance, that substance is a primary irritant under the specified conditions.² Irritants may cause lesions ranging from erythema to deep necrosis of the skin (Fig 3). Primary irritants can comprise mechanical and physical agents and powerful chemicals, including acids,

FIGURE 4 Case of J S, a Leather-Heel Trimmer
Sensitization produced an eruption simulating nummular eczema

gens" or "allergenic substances." The Committee on Industrial Dermatoses has defined a sensitizer as one that increases the capacity of the tissue to react to subsequent exposure. In my experience hypersensitivity to a single allergen occurs in only a few industries. This group of sufferers constitutes the chief problem in occupational dermatology. A carefully taken history of any previous cutaneous disease is most important, in my experience, about 7 per cent of patients have had previous attacks.

Primary irritants that are also sensitizers are essential oils, acids (carbolic, chromic and oxalic) alkalies, soap, cement, lime, various salts — such as the chromates, sulfates, arsenates and nitrates — solvents and the miscellaneous group previously mentioned (Fig 4). The variation of the incuba-

tion period is misleading it may range from several days to many years. In this group patch tests may be of value, and the patient usually has to seek other employment. The longer the incubation period or time of exposure, the greater the sensitization and the more difficult the cure, because these patients become polysensitized. Therefore, medication must be carefully selected, outside activities curtailed, the use of soap and water prohibited and even a dietary regime imposed, for the use of stimulants and improper diet prolongs the disability. The onset is slow and insidious, and the skin frequently presents a somewhat characteristic appearance, except for the hypersensitivity, there is no permanent stigma, such as scarring. This hypersensitivity does not remain specific.

The workers become subjects of controversy before industrial-accident boards for the rest of their occupational existence. They are the ones told not to return to their previous occupation and to avoid exposure to wet work and the use of soap and water — in other words, to refrain from some of the normal activities of life. By law, this hypersensitivity is not compensable, the worker must seek other employment and avoid the substance that might produce a new attack. If this new attack occurs at home or under self-employment, there is no redress, if it occurs while he is working for a new employer, the responsibility for medical care and compensation rests on him. If the worker testifies under oath that some traces of the original eruption remain over a period of several years, the original employer or his insurer is responsible. It sounds simple, but clever lawyers can make the rendering of an impartial decision extremely difficult. The injured employee listens, dazed with the conflicting testimony. He may, however, amaze the attending physician, employed by the insurer, who, properly proud of having cured a difficult eruption, has to listen to criticism of his efforts and accusations against his integrity. The timely use of soap and water or chemicals or friction just before the hearing is sometimes a matter of consternation to the attending physician, who a few days or weeks previously had reported that the patient was well. During the war these cases were extremely rare, but now they are increasing and occur mostly among female workers who have returned to the role of housewives or who have married and find the compensation a useful adjunct to the household budget. Perhaps there is some justification for their position, but we must realize that the largest group of occupational dermatoses is among housewives, who comprise nearly 30 per cent of my private practice, practically all these cases are due entirely to household activities, exposure to soap and soap powders, squeezing oranges, handling raw vegetables and fruit, canning and many of the other activities of the active mother (for 95 per cent of these women have children). These are persons who have never had outside industrial con-

tacts, so that it is just as probable that the plaintiffs were victims of their own household exposures. I believe that the proper way to dispose of these cases would be a reasonable lump-sum settlement, for as O'Donovan⁴ states there is nothing more curative than the golden ointment of compensation.

Characteristic lesions may appear from exposure to these sensitizers or allergens, producing the so-called "allergic dermatitis" or eczema. These are inflammations of the skin due to repeated exposure to substances that are normally innocuous (Fig. 5).

FIGURE 5 Case of H. M., a Shoe Dresser

Eruption frequently seen in shoe dressers and tanners from contact with irritating chemicals

Chlorinated hydrocarbons usually produce characteristic mechanical and follicular plugging with comedones and cysts, but occasionally an allergic reaction consisting of a diffuse erythema is seen on the face, hands and arms of chemists after repeated experimentation. This erythema fades, the skin desquamates, and finally the characteristic comedones and cysts appear as the result of condensation of chloro compounds in the follicles. A similar combination of mechanical or primary irritation and sensitization reaction is seen in workers who use soluble cutting oils. The sensitization is due to the sulfuric acid and the preservatives in the oils.

Reactive and sensitizing dusts frequently cause symptoms and signs similar to those produced by cosmetics, such as face powders and nail polish.

There is itching of the eyelids and the sides of the neck, later, other parts of the exposed skin become affected. The skin is dry, red and scaly, and continued exposure causes edema of the eyelids. As the patient becomes more sensitized the edema appears, and fine papules and vesicles are superimposed.

Workers whose hands are constantly wet develop maceration of the interdigital skin and a sensitivity to the chief ingredient in the solution, whether it is soap, a fruit or a vegetable. I have seen positive patch-test reactions from carrots, lettuce and tomatoes. These eruptions usually start in the webs of the fingers and spread over the backs of the hands and on to the anterior aspect of the wrists. There is a "boiled-out" appearance of the interdigital interspaces, with erythema and vesiculation of the remaining areas. The eruption rarely spreads beyond these areas unless overtreated, and is usually complicated by secondary infection, such as pyogenic bacteria or yeastlike organisms.

Sensitivity to chromates and bichromates, which may be polymorphous in character, presenting oval or round patches, is frequently seen in shipyard workers in contact with a dull-green paint. These patches are described by Hall,⁷ who attributes them to contact with the zinc chromate primer in the paint. He was able to differentiate the eruptions from zinc chromate and those from resin. The latter causes a dermatitis on the sides of the neck, consisting of oval, dull-red, finely squamous, palpable plaques whose long axes are parallel to the lines of cleavage of the skin, as in pityriasis rosea, whereas the former causes nummular and eczematous plaques. The most interesting eruption was one seen at the beginning of the recent war among the enlisted personnel in the Navy and Coast Guard. It appeared on the dorsa of the hands, near the wrists, and on the outer lateral aspects of the extremities. The primary lesions were vesicles, which later became grouped, forming elevated, circular, red, vesicular and oozing patches that tended to clear in the center. These eruptions resembled nummular eczema and were frequently so diagnosed. Patch tests proved that they were caused by the cloth of the uniform, due to a bichromate used as a mordant. A similar eruption appeared among stitchers of this cloth.

Workers highly sensitized to gasoline may show a generalized eruption consisting of erythema and patches of grouped vesicles similar to a dermatitis herpetiformis. Male workers in garages and places where there are poor working conditions, such as dirty floors, frequently present eruptions that start on the dorsa of the feet and about the ankles, spreading up the legs. Rubber finger cots may cause an intensely pruritic, pink, scaly eruption at the site of contact, and heavy rubber gloves may cause a colorless, fine, papular eruption. Dye may produce nothing but an intense edema followed by desquamation. Even the most expert diagnosticians, however, can-

not depend alone on observation, for most contact eczemas are similar in appearance, and a complete history and patch testing are usually necessary to prove the original cause. When other cases result from the same exposure, the cutaneous disturbance is readily recognized. Experience is the best teacher.

DISABILITY

All insurers' medical reports request that the physician express an opinion regarding disability—whether it is total or partial, permanent or temporary. What constitutes disability? The insurer recognizes the fact that if an injury occurs in the course of employment and produces an extensive dermatitis, the worker is temporarily totally disabled. When the accomplishments of blind veterans and those without limbs are considered, however, it seems incongruous to state that the dermatitis of the right index finger of the maker of rubber coats is totally disabling. But this injury destroys his earning capacity, for his work is done chiefly with this finger, by union regulations he is allowed to do no other work, not even to use a brush.

If a stenographer suffers a slight abrasion on the hand from the corner of the desk, the injury is not disabling and hence not compensable. If, however, the plant nurse applies a sulfonamide and the hand becomes swollen so that the patient is unable to type, she is entitled to compensation. If on a warm summer day, with her employer's permission, she eats lunch on the premises of the plant and suffers on her legs a dermatitis from poison ivy, or if she takes a short cut through the plant grounds and suffers intense swelling of the legs so that she cannot get to work, she is entitled to compensation. The same situation in a neighboring field, however, is not recognized as arising out of or in the course of employment and is therefore not compensable. The eruption on the fingers of a soda-fountain clerk is not totally disabling, because she can be put on dry work and treated without loss of time.

The disability from a true occupational dermatitis is never permanent, except for hypersensitivity, because all such dermatitides are curable. It has been ruled by the Massachusetts Supreme Court that sensitivity is not compensable, the worker must seek other work.

A disfiguring scar or a repulsive chloracne of the face lessens the worker's earning capacity in the labor market, and he should therefore be compensated, irrespective of his ability to work. In the Fennell case the employee sustained an injury to the left eye resulting in total loss of vision in that eye, and in such a change in appearance from the right eye that in turning the left eye its abnormal condition was apparent. Despite his testimony that he could do his work better after the accident because he was more careful, he was awarded compensation. The Industrial Accident Board concluded that total inability to do work and total in-

capacity to earn wages for work done are not synonymous, and that total incapacity is present if the employee in the case at bar, on account of the appearance of his eye, is unable to obtain work. Compensation is allowable when there is an impairment of earning capacity. When an employee is disabled from doing some kinds of work and is unable to obtain work of the type he is able to do, a finding of total incapacity is warranted (*Sullivan* 218 Massachusetts 141). On principle, when a worker is unable to obtain other employment because of visible, physical results of an industrial accident, his earning capacity is as much impaired as if he were physically disabled to the extent that he could do no work (*Fennell* 289 Massachusetts 89, 1935).

Statutes in many other states provide payment for disfigurement, without evidence that it results in loss of earning capacity, but in a few states, including Massachusetts, there is no such provision, and only when it interferes with earning capacity can disfigurement be made the basis of an award. In *Streeting v. American Knife Company* (226 New York 199, 1919), in which an explosion disfigured the employee's nose and face, the New York court held that "serious facial disfigurement has a tendency to impair the earning power of its victims," although in New York payment is provided, by statute, for disfigurement. Courts and industrial accident boards recognize the difficulty encountered by the maimed, crippled or disfigured employee. An actress or waitress left with repulsive scars, preventing her from obtaining employment, has lost her earning capacity as much as if she were actually bedridden. As a matter of fact, the Pennsylvania Court, in *Naughton v. Keil* (154 Pennsylvania Superior Court 318, 1944) and in *Eckley v. Rae* (128 Pennsylvania Superior Court 577, 1937), followed this theory, and in the latter case stated specifically, "It is a matter of common knowledge that there is a general disinclination on the part of employers to give work to cripples."

Beard cites a case tried before the Industrial Accident Board, that of *Lillie Hendricks v. Chesterfield Laundry Service Company*. This employee was a thirty-one-year-old Negress who was operating a laundry pressing machine. A part of the machine weighing about 50 pounds shut down on her right forearm, burning her. She managed to free herself and then fainted. In treatment, a dye that formed a firm eschar over the wound was used. It slowly loosened around the edges, and for a time a new dye was applied to the raw areas. As the coagulum was gradually removed ointment was applied, until finally a granulating surface was obtained. The large open surface was then filled in with skin grafting. This graft took fairly well, except that where it crossed the wrist joint there was some stiffness and cracking due to the motion of the joint at that point. The important feature of the case, however, was that the patient was left with an

extensive keloid formation, which disfigured her arm. The employee testified at the hearing that she was sent from an employment agency to two different families to do housework. The prospective employers kept looking at her arm, and the agency was notified after each interview that she had not been hired because the scar was considered obnoxious. The Commissioner found that this constituted a disability and awarded compensation, which the insurer paid without appeal to the courts.

TREATMENT

Treatment of occupational dermatoses begins with the elimination of the causative factor. The ideal method is that of prevention, achieved in the first place by not allowing a potential hazard in the industrial process. Such elimination will never be possible in industry, however, because there will always be essential chemicals that affect a certain number of workers. These possible irritants or sensitizers should be properly labeled so that due precaution against harmful reactions can be taken. Education of the worker regarding care in handling such substances and the installation of facilities for the proper method of cleansing the skin after work are invaluable. Many workers have sustained eruptions from using gasoline, thinner, turpentine or harsh soaps on the skin to remove the day's grime. Supervision is necessary, because workers are apt to refuse to work with gloves or will take unnecessary short cuts in their work, and carelessness causes considerable trouble. A chemist was seen who extracted cashew-nut-shell oil, a notorious primary irritant and sensitizer. During the process of extraction he was careful, wearing a mask, protective clothing and gauntlet rubber gloves, but when the extraction was completed he thoughtlessly discarded them and washed the utensils with his bare hands with a resulting dermatitis.

Early and correct diagnosis of an occupational eruption is most important. If the exact causative factor is easily recognized, removal of the hazard or protection of the worker from any possible contact, together with soothing applications, may be sufficient to prevent disability. If the worker is new on the job an attempt should be made to keep him on it, for if he can survive the first few weeks he may become more or less immune, as many have done. Such workers should be kept under close observation and removed from the work if the eruption spreads.

Twenty-five years of practice in industrial dermatology has produced experience that frequently clashes with papers and books on the subject of returning to work. Records in my office on industrial patients observed over a period of twenty years show that about 50 per cent returned to their old jobs. By exercising due care they were able to work for periods ranging from one to five years without a new attack, and the new attack fre-

quently followed an illness or a vacation. One baker has lost no time despite periodic attacks of baker's eczema for over ten years. His sensitivities have varied, at one time being due to the improver, at another to cinnamon and later to a combination of salt and lard. At times the face, hands and arms have been involved, but the eruption has never spread to other parts of the body. Other patients who previously presented occupational dermatoses have returned to my office with other forms of eruption, such as sensitization due to medication used in the treatment of trivial injuries, or secondary infection following a slight break in the skin.

Many occupational dermatoses arise not from the occupational exposure alone but from a combination of factors, examples of such patients are the man who paints at work and also at home, and the waitress who works all day and then does her housework. Many occupational dermatoses would not occur but for some intervening factor such as those just mentioned, intercurrent illness and internal medication, excessive fatigue or neglected injuries to the skin. These lower the threshold of resistance, and when the patient is relieved and these factors have been eliminated, the threshold rises and many workers can resume their work with impunity.

Anderson⁹ elaborates on a suggestion made several years ago: the use of mild soothing solutions with a slight increase in the reaction in the presence of acids and a decrease in the presence of alkalis.¹⁰ He states that four different points of attack can be applied to the problem of chemical neutralization of a cutaneous irritant. In the first place, direct chemical neutralization may be used, a corrosive and irritant alkali can be neutralized by a weak acid, such as acetic acid (vinegar) or citric acid (lemon juice). The same principle is involved in the use of weak alkalis in the neutralization of irritant acids. Secondly, one may detoxify the chemical irritant by another chemical, which reacts to form an insoluble or nonirritating compound. Thus, chromium compounds can be oxidized into innocuous metallic salts by sodium sulfite. Thirdly, the chemical phenomenon of absorption may be employed. Medications based on this phenomenon are the absorbent powders, such as charcoal and kaolin. Finally, the unusual emulsifying and detergent properties of the new synthetic wetting agents may be used to remove toxic chemicals from the skin. These suggestions are valuable if the causative factor is recognized immediately and the proper treatment is instituted. If a neutralizing solution is not available, plenty of water will dilute the irritant.

Wet dressings should be the first topical remedy. A 5 per cent solution of sodium hyposulfite, either hot or cold, is used in the treatment of poisoning from dyes and chromates. Wet dressings of physiologic saline solution are soothing. When there is only redness and swelling, a saturated solution of magnesium sulfate will produce quick results. When

the skin is red, swollen and vesicular, a 5 per cent solution of aluminum acetate or 2 per cent solution of boric acid, either separately or combined, is extremely valuable, antipruritic and cooling and permits proper drainage. These dressings should be composed of heavy gauze or strips of Turkish towel-ling that have been boiled. They should be changed frequently to remove the debris and allow evaporation. Wet dressings of boric acid, citric acid or citrates may be applied to the so-called "cyanide rash" occasionally seen in jewelers. In the acute stages of cutting-oil folliculitis, the use of wet dressings of 25 per cent isopropyl alcohol has been beneficial. Potassium permanganate in a 1:4500 solution and 0.125 to 0.25 per cent of silver nitrate may be employed when there is secondary infection. Boiled milk (four parts) and lime water (one part) are soothing in cases of dermatitis about the orbits and sides of the neck, such as occurs from exposure to irritating dusts, fumes and resins.

Powders cool and dry the skin, and while protecting it from external irritation permit heat radiation. The combination of alternate wet dressings and dusting of the surface with powder quickly relieves the congestion. The mineral powders are better than the vegetable. The former—kaolin, bismuth compounds, magnesium and calcium carbonates, zinc oxide and zinc stearate—are absorptive and clean and are valuable when there is considerable weeping. Vegetable powders should be used only in combination with mineral powder, because of their tendency to swell and decompose. Wet dressings alone should not be applied for more than twenty-four to forty-eight hours, because they cause maceration. The combination of wet dressings and powders should not be employed for more than seventy-two hours.

If powders are used too long, they tend to cake and to interfere with secretions so that reactions of hypersensitivity or autosensitization appear, or they predispose to pyogenic infection, with the formation of intrafollicular pustules or lymphangitis.

If there is no marked redness or swelling, lotions may be applied immediately or within twenty-four hours. For a universal standby, Calamine Lotion (*National Formulary*), with 1 per cent phenol, is useful, but the physician should not limit himself to a single prescription, for as each eruption and skin varies, so should the local application. Properly prescribed and applied, lotions produce the best results and testify to the therapeutic skill of the physician, the pharmaceutical ability of the chemist and the training of the nursing attendant. Careful directions should accompany the prescription. Being a suspension of powder in fluid, it should be shaken well and spread or evenly sprayed over the skin. A soft paint brush or spray gun is advantageous when the surface is extensive. Glycerin is valuable because of its power to absorb moisture, but it retains the moisture and therefore should be

omitted in cold weather, because it makes the skin feel cold and sticky. I have used the formulas* referred to below in the treatment of various occupational dermatoses. When there is considerable secretion and danger of infection from the nature of the work (such as sensitization from soluble cutting oils), the following formula is useful:

SUBSTANCE	AMOUNT
Calamine	20 gm
Zinc oxide	20 gm
Boric acid	10 gm
Glycerin	2 cc
Bentonite	2 gm
Lime water (as needed) to make a solution of	20 cc

Bentonite is a colloidal clay that acts as a medium for suspending the powders in the liquid by producing a gel. For the erythematous, squamous eruption, such as that seen after contact with irritating dusts, fumes or resins, the following may be used:

SUBSTANCE	AMOUNT
Phenol	2 gm
Zinc oxide	0 gm
Calamine	10 gm
Starch	10 gm
Glycerin	10 cc
Distilled water (as needed) to make a solution of	250 cc

When there is marked pruritus, additional antipruritics may be added, such as the following:

SUBSTANCE	AMOUNT
Menthol	0.6 gm
Phenol	1.2 gm
Solution of coal tar	8.0 cc
Calamine lotion (A-F as needed) to make a solution of	200 cc

Coal tar solution is much more satisfactory for the preparation of lotions and liniments if made with 70 per cent alcohol instead of 95 per cent. The addition of the cuticolored neocalamine in sufficient amount to match the patient's skin makes a more pleasing preparation. Neocalamine, however, stains clothing and bed linen. For the relief of an intensely itchy follicular eruption, seen after contact with rubber or mica, when there is no evidence of infection, the following lotions are valuable:

SUBSTANCE	AMOUNT
Menthol	0.6 gm
Phenol	1.2 gm
Solution of coal tar	10.0 cc
Zinc oxide	20.0 gm
Talc	20.0 gm
Glycerin	15.0 cc
Alcohol (35 per cent, as needed) to make a solution of	250.0 cc
Menthol	0.5 gm
Solution of coal tar	15.0 cc
Glycerin	10.0 cc

*Many of these formulas were developed with the collaboration of Leslie M. Osmar and Mitchell J. Stoklosa, of the Department of Pharmacy, Massachusetts College of Pharmacy, Boston.

Witch hazel	100.0 cc
Solution of boric acid (as needed) to make a solution of	240.0 cc
Solution of coal tar	2.0 cc
Phenol	2.0 gm
Menthol	0.3 gm
Boric acid	1.5 gm
Witch hazel	100.0 cc
Alcohol (70 per cent, as needed) to make a solution of	250.0 cc

Isopropyl alcohol, being much less expensive, can be substituted for the alcohol.

The following is an old reliable prescription for dry, chapped hands and fingers:

SUBSTANCE	AMOUNT
Tincture of benzoin	15 cc
Glycerin	10 cc
Rose water (as needed) to make a solution of	250 cc

When the lips become chapped and fissured, bathing with the following is beneficial:

SUBSTANCE	AMOUNT
Sodium borate	6 gm
Tincture of myrrh	20 cc
Water (as needed) to make a solution of	250 cc

When the skin becomes crusted, it should be bathed with equal parts of a 2 per cent solution of boric acid and a 10 per cent solution of aluminum acetate until the crusts soften and become detached. They should not be removed forcibly. Pastes are then indicated, the acute inflammation having subsided. Their action is more prolonged and protective, and they adhere to and soften the scales and crusts.¹¹ A paste is a rather stiff preparation consisting of powders and the vehicle, which may be glycerin, hydrocarbons, paraffin, petrolatum or animal or vegetable fats. Those containing glycerin are watery pastes, such as the following:

SUBSTANCE	AMOUNT
Starch	12 gm
Distilled water	24 cc
Glycerin (as needed) to make a solution of	120 cc
Zinc oxide	30 gm
Talc	30 gm
Glycerin	30 cc
Distilled water	30 cc

The most popular pastes are those having a base of petrolatum, such as the official paste of zinc oxide containing equal parts of zinc oxide and powdered starch and 50 per cent of fat. On hairy surfaces, zinc oxide is apt to cause a folliculitis, in which event its proportion should be reduced. The following formulas are suggested:

SUBSTANCE	AMOUNT
Zinc oxide	2 gm
Starch	15 gm
Petrolatum	15 gm
Solution of aluminum acetate	10 cc
Lanolin	30 gm
Zinc oxide paste	30 gm

If itching persists in this subacute stage, one of the antipruritic lotions should be applied before the paste

To avoid the necessity of two topical applications, a mixture of lotion and oil — that is, a liniment or emulsion — is used. Calamine Liniment (*National Formulary VII*) and Neocalamine Liniment (*National Formulary VII*) are excellent examples

SUBSTANCE	AMOUNT
Prepared calamine	15 gm
Zinc oxide	15 gm
Olive oil	125 cc
Solution of calcium hydroxide (as needed) to make a solution of	250 cc
Prepared neocalamine	30 gm
Olive oil	100 cc
Solution of calcium hydroxide (as needed) to make a solution of	250 cc

Mineral oil may be substituted in the above prescriptions if, as sometimes happens, the patient is hypersensitive to olive oil or because of its shortage or expense. Various antipruritics can be added

SUBSTANCE	AMOUNT
Solution of coal tar	8 cc.
Calamine liniment (<i>N E VII</i> , as needed) to make a solution of	250 cc

If there is any evidence of pyogenic infection the following formula can be prescribed

SUBSTANCE	AMOUNT
Menthol	0.5 gm
Phenol	1.0 gm
Ichthammol	7.5 gm
Zinc oxide	30.0 gm
Olive oil	100.0 cc
Lime water (as needed) to make a solution of	250.0 cc

In prescribing liniments other than those of the *National Formulary*, it is well to advise the pharmacist to use an electric mixer. Wetting agents, such as sodium lauryl sulfate, are valuable additions to liniments. Their effectiveness is based on their power to reduce surface tension between the solid and the solvent, thus permitting penetration and dispersion of the solid. The following formula is smooth and efficient

SUBSTANCE	AMOUNT
Zinc oxide	15.0 gm
Calamine	15.0 gm
Olive oil	60.0 cc
Sodium lauryl sulfate	5.0 gm
Phenol	0.5 gm
Water (as needed) to make a solution of	250.0 cc

In persistent infiltrated extensive areas in which there is no evidence of infection, tar is useful, but it should be employed sparingly and only in the late stages. Liniments are of most benefit in an extensive eruption due to sensitization when the vesiculation has ceased, the crusts have become detached and the skin is red, dry and pruritic — that is, after the acute stage has subsided

The majority of occupational dermatoses should be cured by the use of wet dressings, lotions and, finally, pastes and emulsions. Creams and ointments cause many of the complications of the treatment of occupational dermatoses. Ointments, especially, having no evaporating properties and being comparatively free from water, cause irritation and congestion when used in the initial stages. They may be employed in the subacute stage or in persistent eruptions. Neocalamine and Calamine Ointment (*National Formulary VII*) are excellent preparations. In fact, if physicians would prescribe more ointments of the *National Formulary*, they would have more expertly compounded prescriptions and less sensitization. When ointments contain drugs such as phenol, mercury, resorcin, Furacin and benzocain, the sulfonamides and penicillin, there is danger of absorption or sensitization. If there is no infection, there is no indication for their use. If secondary infection occurs, these drugs may be employed with caution and rarely for over one week, for by that time the infection should be relieved

Ordinarily, an occupational dermatosis needs no internal therapy. When there is secondary infection, however, a sulfonamide or penicillin may be indicated. I prefer 50,000 units of penicillin in physiologic saline solution intramuscularly every three hours, it should be given no longer than five days, because that period is usually sufficient and sensitization is avoided. A dosage of 300,000 units of penicillin in wax and peanut oil daily is also useful, but the possibility of sensitization is increased by allergenic properties of the peanut oil. Benadryl and Pyribenzamine should be given during the period of injection. They have been helpful in controlling the spread and itching in the sensitization type of occupational dermatoses. If the patient is working, Benadryl should not be given because of its tendency to cause drowsiness. I prefer Pyribenzamine, which seemed to be of value in a few cases of industrial dermatitis. Autohemotherapy, alone or combined with previous intravenous injections of calcium gluconate, apparently helps when there is considerable edema or rapid extension of the eruption

Some readers may criticize this array of formulas. Everyone knows that a normal skin may prefer one soap to another, usually owing to the difference in the reaction or to the amount of free alkali present, or a woman may try a dozen face powders before she finds one suitable to her skin. How much more important is topical application prescribed for the injured or traumatized skin! Frequently, a patient states that irritation or no relief resulted after the use of calamine lotion, but when she is persuaded to use the same lotion modified by the addition of boric acid, talc or starch or coal-tar solution, an immediately soothing response is obtained. A resourceful and successful therapist must have many topical applications at his com-

ment to obtain results in treating the various dermatoses. Expert knowledge of the medication and methods of using a few prescriptions is all that is necessary for the majority of cases, but it is the few that try one's patience and test one's therapeutic ability. With removal of the cause and with proper treatment and proper co-operation on the part of the patient, all industrial dermatoses can be cured.

* * *

Two and a half centuries after Ramazzini described the case of a young gilder who died from mercurial poisoning from inhalation, I saw a fatal case in a young woman — a pioneer worker in a new industry — who died from such exposure. That exposure has been eliminated after loss of a human life, which might have been prevented if the manufacturers had known of the danger of mercurial poisoning and had taken precautions against it.

Severe injuries have resulted from the use of x-rays in industry. Their use has been continued, but proper precautions are taken to prevent harmful effects. So, too, with the introduction of new processes as a result of the discovery of the atomic bomb. Today, practically all known elements can be made temporarily radioactive by means of the cyclotron. Proper medical supervision by industrial experts

may prevent serious industrial dermatoses such as cancer of the skin, which is one of the aftermaths of excessive exposure to radiation.

The general practitioner cannot be expected to keep abreast of the rapid changes in industrial chemistry and physics, such as the radioactive substances. He must necessarily rely on industrial experts for information. With the vast amount of literature on medical therapy, however, he should know the indications and method of use of recent antibiotics and drugs.

THE HEPATITIS OF HYPERTHERMIA

Report of a Fatal Case

JOSEPH H. BRAGDON, M.D.*

BOSTON

PATIENTS receiving intensive artificial fever therapy occasionally develop jaundice. This phenomenon has recently been reported as a major complication of therapeutic hyperthermia by several different groups of observers.¹⁻³ In the reported series the incidence of jaundice has been as high as 19 per cent.⁴

The jaundiced patients follow a characteristic clinical course. Usually within the first twenty-four hours following fever, exaggerated nausea and vomiting occur. Within forty-eight hours the urine is dark and jaundice becomes apparent. There may be upper abdominal discomfort and tenderness over the liver. Fever, if present, is slight. In the great majority of cases the jaundice promptly disappears, usually within a week, and the patient rapidly recovers from the accompanying symptoms.

Although there is general agreement that the jaundice is the result of liver damage rather than of excessive blood destruction, divergent opinions

have been expressed concerning the pathogenesis of the underlying hepatic disorder. The theory propounded by Brown et al.⁴ — that inadequate replacement of salt and water is chiefly responsible for the jaundice — is widely held by those using artificial fever. MacDonald⁵ suspected the sulfonamides, which are frequently administered simultaneously. More recently speculation has centered on the possibility of a virus etiology.

Descriptions of the histopathology of the liver could be found in only 2 cases, presumably because the syndrome is rarely fatal. Both descriptions are brief and lack illustrations. Wilbur and Stevens⁶ reported their findings in a patient who received artificial fever therapy, developed jaundice and died on the third day after treatment, the liver weighed 2350 gm and showed a diffuse early necrosis. Chunn and Kirkpatrick⁷ described a similar case in which death occurred on the fourth day after fever and examination revealed a liver weighing only 1320 gm and showing extensive atrophy.

Autohemotherapy, alone or combined with previous intravenous injections of calcium gluconate, apparently helps when there is considerable edema or rapid extension of the eruption.

Some readers may criticize this array of formulas. Everyone knows that a normal skin may prefer one soap to another, usually owing to the difference in the reaction or to the amount of free alkali present, or a woman may try a dozen face powders before she finds one suitable to her skin. How much more important is topical application prescribed for the injured or traumatized skin. Frequently, a patient states that irritation or no relief resulted after the use of calamine lotion, but when she is persuaded to use the same lotion modified by the addition of boric acid, talc or starch or a coal-tar solution, an immediately soothing response is obtained. A resourceful and successful therapist must have many topical applications at his com-

similar. The capsules were smooth. The parenchyma was pale and bulging with edema. The renal pelvis, as well as the remainder of the genitourinary system, were not abnormal.

Microscopically in addition to marked interstitial edema and an occasional small hemorrhage there was precipitated protein throughout all portions of each nephron (Fig. 3). The outstanding abnormalities were observed in the distal convoluted and collecting tubules many of which showed necrosis and varying stages of regeneration. The latter process predominated. Many of these tubules contained

sized in two recent reviews of the subject.^{13, 14} That the sulfonamides play no part in the production of post-hyperthermia hepatitis was demonstrated by Wallace and Bushby,¹⁵ who showed that the incidence of jaundice was no greater among patients simultaneously receiving sulfonamides than among those not receiving them.

The possibility that the hepatitis of hyperthermia is of virus origin has occurred to several observers. Such a concept presupposes the presence of a hepatotoxic agent latent in the body and in some way activated by the treatment. Fever therapy was repeated in 2 of MacDonald's³ jaundiced patients and in 1 of our own. In no case did clinical jaundice reappear after the second treatment.

The virus of herpes simplex is harbored by many people, and when the proper stimulus—including heat—is forthcoming, clinical herpes appears. Herpes labialis has always been a common complication of artificial fever therapy. It occurred in 66 per cent of our own cases. Although the intranuclear inclusions found in the liver in the case presented above are indistinguishable from those found in herpes simplex infections, this does not imply a herpetic or even a virus etiology for the

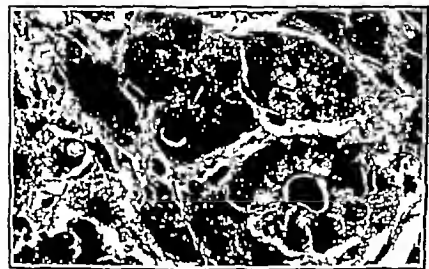

FIGURE 2 Intranuclear Inclusion Body in Liver Cell

intraluminal masses of red brown material—so-called pigment casts. In places these were surrounded by polymorphonuclear and histiocytic phagocytes. A few tubular cells contained intracytoplasmic droplets of yellow-green material resembling bile pigment. No inclusion bodies were found.

There was some edema of the lungs and brain but no other significant abnormality.
